PROSPECTS IN PSYCHIATRIC RESEARCH

The Proceedings of the Oxford Conference of the Mental Health Research Fund, March, 1952

Edited by J. M. TANNER

In March 1952, The Mental Health Research Fund convened a Conference at Magdalen College, Oxford, to discuss what ignorances principally hamper our understanding of mental illness. The Conference consisted of some fifty invited research workers and doctors all of them men of considerable eminence in their fields. This book presents the proceedings of the Conference.

THE EXTRA PHARMACOPŒIA
(MARTINDALE)
Volume I, 23rd edition

This new edition, completely re-written, provides new as well as old information on the thousand and one s used in medical practice. It supplies the most complete guide available to "ethical" proprietaries and preparations in foreign pharmacopœias.

For the first time it incorporates "Squire's Companion." The book has been entirely reset with a larger size and more pages than any previous edition.

Pp. xxii + 1352. Price 55s. (Postage 1s.)

Remittance with order is requested

A new approach to 'khellinisation'

KHELLANALS

suppositories 'Pabyrn'

Khellin therapy without nausea.

A non-toxic form of pure khellin providing effective treatment in chronic bronchitis, bronchial asthma, angina pectoris, renal colic — without the distressing side-effects so common to parenteral and oral administration.

Clinical sample and literature on request

PAINES & BYRNE LTD., Pabyrn Laboratories, Greenford

Telegrams GLANDS, GREENFORD Telephones PERIVALE 1143 (5 lines)

MARMITE

yeast extract

is a useful adjunct in certain special diets where the B vitamins are particularly needed.

In restricted diets, such as reducing and diabetic diets, some foods that supply the B vitamins are only allowed in limited quantities and another source of these vitamins must be introduced

Marmite yeast extract supplies 1.5 mg per oz of riboflavin and 16.5 mg per oz. of nicotinic acid and also the less well-known B_2 factors Its carbohydrate content is negligible and it is therefore of special value for inclusion in diabetic diets

Obtainable from chemists and grocers

Special terms for packs for hospitals welfare centres and schools

Literature on request

The Marmite Food Extract Co Ltd, 35 Seething Lane London, E.C.3

It's not the first cost that matters........

When buying syringes, quality and the cost of replacements must be taken into account Though 'Plim' syringes cost more at first than the ordinary kind, they are far more economical in the long run For these reasons

1. The strong protective metal casing of the glass barrel reduces breakage to a minimum
2. If breakage does occur, you need replace only the barrel and piston, instead of buying a complete syringe This means a saving of about 50 per cent. compared with ordinary syringes

Apart from the economy of 'Plim' syringes, they possess other important features —

Perfect fit of piston to barrel
Accurate calibration • *Precision manufacture*
Individually-fitted pistons No solder or cement
Sterilisation up to 250C

SIZES 1 2 5 10 and 20 c.c
INTERCHANGEABLE NEEDLE FITTINGS
Record Luer and all other types Side and central.

DEHYDROCHOLIN B.D.H.

For the treatment of 'bilious' and 'liverish' conditions associated with biliary insufficiency. Dehydrocholin B.D.H. is also useful in establishing normal bowel action in patients with a deficiency of bile and in patients needing mild peristaltic stimulation.

Dosage of three tablets three times a day is recommended.

Tablets containing 0.25 gramme in bottles of 20 and 100

Literature and samples are available to physicians on request.

NEW BAILLIÈRE BOOKS

MODERN TREATMENT YEARBOOK 1953

"The editor has again succeeded in covering a tremendous lot of ground, and the practitioner, whose daily working ground this is, will welcome these latest maps to help him the hardiest skimmer is soon deep in the very article, up-to-date and clear, that he has so long been looking for" —*The Lancet*

MODERN TREATMENT YEARBOOK 1953

"An excellent yearbook, highly authoritative and up-to-date we congratulate the editor on providing the profession with a most helpful book and we recommend it to all who desire to keep abreast with recent developments in treatment"—*The Postgraduate Medical Journal*

Pp. viii + 334. 38 Articles 39 plates *Postage 1s* **21s.**

Edited by **SIR CECIL WAKELEY,** BT, K B E, C B., LL.D, M Ch, D Sc, P R C S, F R S E, F R S A, F A C S, F R A C S

NINETEENTH YEAR OF ISSUE

A Modern Practice of OBSTETRICS

D M Stern, M A, M.B, B Ch, F R C S, F R C O G, and C W F Burnett, M D, F.R C S, F R C O G

A fully illustrated guide to modern obstetrical practice, based upon many years' hospital experience The diagnosis and management of all normal and common abnormal conditions are fully covered, with sufficient description of the rarer complications to enable accurate diagnosis to be made The illustrations have been specially drawn for the book, and their clarity and detail add greatly to its value as an instructive and practical manual

Pp. viii + 250, with 144 illustrations. Postage 1s. 3d **35s.**

THORACIC SURGICAL MANAGEMENT

J R. Belcher, M S, F R C S, and I W B Grant, M B, F R C.P

Intended for all who may have thoracic surgical cases under their care, this book gives details and descriptions of the numerous procedures used in the investigation and post-operative treatment of such cases, drawing upon many years' practical hospital experience and incorporating in one volume information and advice which must usually be obtained from many sources

Pp. viii + 200, with 64 illustrations. Postage 1s **16s.**

Recent New Editions of Standard Works include

ROSE & CARLESS' Manual of Surgery

18th Edition, edited by SIR CECIL WAKELEY, Bt, K B E, C B, LL D, M Ch, D Sc, P R C S Pp xx + 1562, with 18 coloured plates and 1007 other illustrations In two volumes
Postage 2s 4d *The set, 63s*

Lake: THE FOOT

4th Edition, by NORMAN C LAKE, M D, M S, D Sc, F R C S Pp vi + 466, with 166 illustrations
Postage 1s *25s*

MacKenna's DISEASES OF THE SKIN

5th Edition, revised and enlarged by R M B MACKENNA, M A, M D, F R C P Pp viii + 604, with 27 coloured plates and 215 other illustrations
Postage 1s 4d 42s

Textbook of Mental Deficiency (Amentia)

THE EARLY DIAGNOSIS OF THE ACUTE ABDOMEN

By Sir ZACHARY COPE, *M.D., M.S., F.R.C.S.*

"Too well known to demand emphasis on its practical value to the general practitioner."—*The Practitioner.*

TENTH EDITION 286 *pages* 39 *illustrations* 15s. *net*

OXFORD UNIVERSITY PRESS

OXFORD MEDICAL PUBLICATIONS

APPLIED PHYSIOLOGY

by SAMSON WRIGHT, *MD, FRCP*

With the collaboration of M MAIZELS, *MD, FRCP*

and J B JEPSON, *MA, BSc, DPhil, ARIC*

'This book has always been held in affectionate regard, particularly by postgraduate students, because it is readable and interesting and the diagrams and figures are clear and simple These features are retained and even improved in the present edition, and are themselves sufficient to put it ahead of most of its contemporaries'—POSTGRADUATE MEDICAL JOURNAL

NINTH EDITION 1206 *pages* 688 *illustrations* 4 *coloured plates* 50s. *net*

THE CLINICAL APPLICATION OF ANTIBIOTICS: PENICILLIN

by M E. FLOREY, *MD*

'It will be an indispensable work of reference for anyone in difficulties over the use of penicillin or who wants to know what it may be expected to achieve in a given condition'—BRITISH MEDICAL JOURNAL

744 *pages* 222 *illustrations* 98 *tables* 84s *net*

TUBERCULOSIS OF BONE AND JOINT

by the late G R. GIRDLESTONE and E W SOMERVILLE, *MB, FRCS(Ed)*

'This is still the standard work on surgical tuberculosis It is indispensable for the specialist working in this particular field, and for the general surgeon who may have to undertake the management of cases of bone and joint tuberculosis'

—THE IRISH JOURNAL OF MEDICAL SCIENCE

SECOND EDITION 322 *pages* 260 *illustrations* 45s *net*

INCREASED DEMANDS

Certain circumstances may cause an increase in the daily requirements of vitamins which is not met by the average diet. In such cases a food supplying the lacking vitamins is often recommended in preference to synthetic vitamin supplements

When an increased demand for the B_2 vitamins arises, Marmite has proved particularly useful as it provides these vitamins in the naturally occurring form in a palatable foodstuff For regular inclusion in the ante-natal diet, Marmite is recognised as being of somewhat special value

Literature on request

MARMITE

yeast extract

contains

Riboflavin (vitamin B_2) 1 5 mg per oz
Niacin (nicotinic acid) 16 5 mg per oz

Obtainable from chemists and grocers

DISABILITIES

AND HOW TO LIVE WITH THEM

by 55 Patients

Demy 8vo 252 pages Price 10s 6d net, plus 6d postage

The writers of these essays are practical people who have found ways of overcoming their various disabilities, and they have written these accounts in order to pass on to others the devices—whether in the form of a tool, a regimen, an outlook, or a way of life—which have helped them Without intending it they pass on something else too their good spirits—and that makes for good reading

COMBINED ACTION

Because the B vitamins appear to act synergistically, many doctors, when prescribing these vitamins, prefer to recommend a natural source which supplies most of the essential factors

As a dietary source of the B vitamins Marmite has been found to be particularly useful, since it supplies riboflavin (1 5 mg per oz) and nicotinic acid (16 5 mg per oz) as well as folic acid, pantothenic acid, pyridoxin, biotin, choline, inositol and *p*-aminobenzoic acid Marmite can be incorporated in the diet in a variety of ways and it is therefore easy to administer adequate quantities

MARMITE
yeast extract

Obtainable from Chemists and Grocers

THE EXTRA PHARMACOPŒIA
(MARTINDALE)
Volume I, 23rd edition

This new edition, completely re-written, provides new as well as old information on the thousand and one drugs used in medical practice. It supplies the most complete guide available to "ethical" proprietaries and to preparations in foreign pharmacopœias.

For the first time it incorporates "Squire's Companion." The book has been entirely reset with a larger page size and more pages than any previous edition.

Pp. xxii + 1352 Price 55s. (Postage 1s.)
Remittance with order is requested

THE PHARMACEUTICAL PRESS, 17, Bloomsbury Square, London, W.C.1
(Publishers of the British Pharmaceutical Codex)

OXFORD MEDICAL PUBLICATIONS

DISEASES OF THE NERVOUS SYSTEM

by SIR RUSSELL BRAIN, *DM, PRCP*

'This book has become one of the most widely used and justly popular textbooks of neurology The fourth edition is worthy of its predecessors'—POSTGRADUATE MEDICAL JOURNAL.

FOURTH EDITION 1034 *pages* 85 *illustrations* **42s.** *net*

THE DIAGNOSIS AND TREATMENT OF INTRATHORACIC NEW GROWTHS

by MAURICE DAVIDSON, *DM, FRCP*

with a chapter on Radiotherapy

by DAVID W SMITHERS, *MD, MRCP, DMR*

and a chapter on Operative Treatment

by OSWALD S. TUBBS, *FRCS*

'This book is comprehensive and authoritative but not unduly specialised It is clearly meant to inform the non-specialist seeking information rather than to be a complete specialist presentation'

—BRITISH JOURNAL OF SURGERY

268 *pages* 172 *illustrations* **42s** *net*

X-RAY INTERPRETATION

by H CECIL H BULL, *MB, MRCP*

with a chapter on Radiography of the Head

by JAMES W D BULL, *MB, MRCP, DMR.*

'This is a book which provides exactly what the clinician requires in order to appreciate the broad details of radiological interpretation'—BRITISH MEDICAL BULLETIN

SECOND EDITION 440 *pages* 287 *illustrations* **25s.** *net*

THE EARLY DIAGNOSIS OF THE ACUTE ABDOMEN

by SIR ZACHARY COPE, *M.D, MS, FRCS*

ESSENTIALS IN DISEASES OF THE CHEST
For Students and Practitioners
by PHILIP ELLMAN, M.D., F.R.C.P.
With a Foreword by Sir Robert A. Young, C.B.E., M.D., F.R.C.P.
'Chest disease is treated as part of general medicine and is brought into relation with other conditions. To have presented such a complete review of the subject in so small a volume and with such admirable clarity is indeed a notable achievement.'
—Tuberculosis Index.

‘TERCIN’

Combines aspirin and phenacetin with a barbiturate

FOR THE RELIEF OF MILD FORMS OF PAIN

Its cost to the National Health Service is no greater than that of Tab. Codein. Co. B.P.

Each tablet contains Aspirin 5 grains Phenacetin 3 grains Butobarbitone ½ grain

Bottles of 200 at 4/10 and 1000 at 24/-
Prices to pharmacists in Great Britain.

THE BRITISH DRUG HOUSES LTD · LONDON N.1

A new combination

CODIS

REGD

soluble aspirin with codeine phosphate and phenacetin

Codis presents a familiar grouping of analgesic drugs, aspirin, phenacetin, codeine phosphate, with an important advantage The "aspirin" in Codis is rendered soluble, as in 'Solprin'

Placed, uncrushed, in water, a Codis tablet disperses in a matter of seconds to form a solution of calcium aspirin and codeine phosphate with finely suspended phenacetin The chance of irritation of the gastric mucosa by undissolved particles of aspirin is thus minimised.

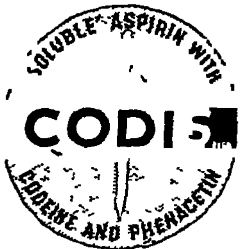
Codis is recommended for all those conditions for which Tab Codein Co B P would be prescribed It has the added advantages of greater ease of administration and far less likelihood of aspirin intolerance, while the rapid absorption of the soluble aspirin promotes prompt relief

COMPOSITION *Each Codis tablet contains Acid Acetylsalicyl B P 4 grs, Phenacet B P 4 grs, Codein Phosph B P 0 125 grs, Calc Carb B P 1 2 grs, Acid Cit B P (Exsic) 0 4 grs, Excip ad 11 45 grs*

Codis is not advertised to the public

DISPENSING PACK (Purchase Tax free) 300 tablets in distinctive gold foils of 6 tablets each 16/6 per box

PUBLIC SIZES Packs of 20 tablets 2/7 each inc P T



RECKITT & COLMAN LTD, HULL AND LONDON (PHARMACEUTICAL DEPT HULL)

Optimum Nutrition

Although severe malnutrition is now seldom seen in this country, there are undoubtedly certain groups whose nutritional standard is low and whose general health could be improved with a better diet.

The protective foods are more often neglected than the other foods by those whose diet is not based on sound principles Marmite, a protective food supplying the B_2 vitamins, is a concentrated yeast extract which is economical as a dietary source of these vitamins

MARMITE

yeast extract

contains

Riboflavin (vitamin B_2) 1 5 mg per oz
Niacin (nicotinic acid) 16 5 mg per oz

Obtainable from chemists and grocers

Special terms for packs for hospitals, welfare centres and schools

METHUEN'S MONOGRAPHS ON BIOCHEMICAL SUBJECTS

New Volume

THE BILE PIGMENTS

by

C. H. GRAY, M D, D Sc, M R C P, F R I C
Professor of Chemical Pathology in the University of London

The aim of this brief monograph is to provide a readable, useful account of the bile pigments, particularly in relation to man, and it is hoped that readers will include pathologists, biochemists, physiologists, and clinicians With the exception of *The Hæmatin Compounds and Bile Pigments*, the standard work of reference by Lemberg and Legge, and one or two brief review articles on specific aspects of the bile pigments there is no up-to-date account of the subject in the English language

With 57 diagrams 9s 6d

METHUEN

LECTURES ON THE SCIENTIFIC BASIS OF MEDICINE

VOLUME I 1951-52

'No medical man, however specialised, could fail to find something to interest him in this book; and many, because of their specialisation perhaps, will want to read it from cover to cover' *The Lancet*

'I believe that most doctors who have preserved the habit of reading would enjoy each and any of the 18 lectures printed in this volume' *British Medical Journal* *Illustrated* 30s *net*

SOME PROBLEMS IN NEUROPHYSIOLOGY

F Bremer

The Professor of General Pathology in the University of Brussels here examines the problems of synaptic transmission, inhibition and autorhythmicity, discusses the evidence leading to fairly definite ideas on the physiological basis of electroencephalography, and gives an account of the electrophysiological investigation of those areas of the cortex involved by acoustic stimuli

Nutrition in Convalescence

It has been suggested that special attention should be paid to pre- and post-operative nutrition During convalescence there may be an increased need for the essential nutrients and particular care should be taken to ensure that the patient receives an adequate supply of these

In planning meals for the convalescent the protective foods are therefore important. Marmite yeast extract supplies essential B_2 vitamins and is especially useful in the convalescent diet, as it adds an appetising flavour to many dishes and can also be served as a drink

MARMITE
yeast extract

Literature on request

contains
Riboflavin (vitamin B_2) 1 5 mg per oz
Niacin (nicotinic acid) 16 5 mg per oz

ANTIPRURITIC FUNGICIDE

Literature and samples available on request from the Medical Department

Epidermophytoses and allied fungoid infections often resist treatment owing to re-infection from scratching and from the poor penetration of the medicament Factors such as these have been considered in the formulation of CALPED CREAM which provides the anti pruritic fungicide parachlorophenylether which is proved to have a very marked inhibitive action on many types of fungi Salicylic acid in the formula contributes to the fungicidal properties of the cream by encouraging desquamation of the infected skin and allowing direct contact to be made with invading fungi CALPED is available in cream and powder form The latter form is presented in a polythene insufflator which facilitates application

FORMULA *CALPED CREAM—Parachlorophenylether 0.5% Phenylmercuric Nitrate 0 004% Acid Salicylic 0 01% in a Bentonite Cream Base*
Available in 2 oz—jars 3/- each plus P T
CALPED POWDER—Parachlorophenylether in a

EXTRASYSTOLES AND ALLIED ARRHYTHMIAS

by

DAVID SCHERF, MD FACP
Associate Professor of Medicine, New York Medical College

and

A. SCHOTT, MD (Heidelberg), MRCS
Medical Officer i/c Cardiographic Dept., Queen Mary's Hospital for the East End

This book, based on the authors' combined experience of thirty years gained in Vienna, New York, and London, gives a comprehensive description of extrasystoles and allied irregularities of cardiac rhythm. It covers all arrhythmias due to disturbances of a dominant rhythm by contractions caused by abnormal impulses. It contains a detailed historical chapter and an exhaustive description of the electrocardiographic appearances of the numerous varieties of extrasystoles, as well as of their relation to physiological principles, nervous system and drugs.

Nutrition in Convalescence

It has been suggested that special attention should be paid to pre- and *post-operative nutrition* *During convalescence* there may be an increased need for the essential nutrients and particular care should be taken to ensure that the patient receives an adequate supply of these

In planning meals for the convalescent the protective foods are therefore important Marmite yeast extract supplies essential B_2 vitamins and is especially useful in the convalescent diet, as it adds an appetising flavour to many dishes and can also be served as a drink

MARMITE
yeast extract

DISC LESIONS for the General Practitioner

JAMES CYRIAX, M.D.

The first publication on disc lesions specially for the general practitioner and student Dr Cyriax deals with the type of case often dismissed as "fibrositis" or "rheumatism," whose treatment is generally as dull for the doctor as it is *unrewarding for the patient*

From this small pamphlet the reader can learn how to assess the history, conduct the clinical examination, make a precise diagnosis and carry out effective treatment Such discs as are not reducible by manipulation are given, together with indications for alternative treatment

INTRACRANIAL HYPOTENSION

FRANCIS PAGE
M.D. Lond., M.R.C.P.
REGISTRAR, PROFESSORIAL MEDICAL UNIT, MIDDLESEX HOSPITAL, LONDON

Magendie (1825) described vertigo and unsteadiness following removal of cerebrospinal fluid (C.S.F.), and attributed them to cerebral anæmia due to pressure on basal blood-vessels by the brain no longer supported by its cushion of C.S.F. Until the early part of the present century the possible clinical importance of a low C.S.F. pressure passed unnoticed. It was then noted that many unconnected medical conditions might be associated with a low C.S.F. pressure, but no specific clinical picture was recognised.

Leriche (1915) described the value of lumbar puncture in head injuries sustained in the war which broke out in 1914. Later (Leriche 1920) he described in detail the clinical picture of intracranial hypotension, discussed its possible causation, and showed the value of subcutaneous serum and intravenous distilled water in treatment. Still later (Leriche 1931) he described his further experience of this condition and stated that little interest had been aroused by his previous reports, although a few cases had been reported by his pupils. Since then many reports, mostly by French workers, have been published on the Continent, but little attention has been paid to intracranial hypotension in this country. This subject was discussed at a combined meeting of the neurological section of the Royal Society of Medicine and the Neurological Society of Paris in 1948 (*Proceedings of the Royal Society of Medicine* 1948). Thorsén (1947) extensively reviewed the published reports of intracranial hypotension following spinal anæsthesia, and Chorobski (1950) discussed intracranial hypotension following cranial operations and suggested its pathogenesis.

In the earlier reports of cases in which a low C.S.F. pressure was found the lack of accurate methods of measuring the pressure detracts from the value of the observations, and it is only since the more general use of manometry that the clinical significance of intracranial hypotension has been realised. Leriche's early suspicions that headaches, vertigo, nausea, convulsions, and stupor sometimes progressing to coma and death could be associated equally with hypotension as with hypertension of the C.S.F. seemed to be supported by the case which he described with Emery (Leriche and Emery 1922):

> "A young man sustained a basal fracture of the skull with escape of cerebrospinal fluid from the ear. When seen the patient was comatose and the loss of cerebrospinal fluid had ceased. Following an intravenous injection of 40 ml. of distilled water the patient rapidly became conscious and talked normally although still complaining of headache and giddiness. At the same time cerebrospinal fluid again spurted from his ear and after a short interval he relapsed into semicoma, the flow of cerebrospinal fluid ceasing. The intravenous injection was twice repeated with similar results and following the third injection the flow of cerebrospinal fluid ceased completely and the patient made an uninterrupted recovery."

Leriche and Wertheimer (1921) described hypotension complicating other closed and compound head injuries, a case of jacksonian epilepsy, and one of generalised epilepsy, in which the intravenous injection of distilled water led either to recovery of consciousness or to cessation of fits. They summarised the causes of cerebral hypotension as:

(1) Diagnostic or therapeutic lumbar puncture and, especially, spinal anæsthesia.

(2) Closed or compound head injuries with or without loss of C.S.F. from the ear.

(3) Cranial operations.

(4) Unrelated medical or neurological disorders.

ÆTIOLOGY

There can be little doubt that most cases of cerebral hypotension fall into Leriche's first three groups, but his fourth group is composed of several apparently unrelated conditions.

Fontan et al. (1946) describe the case of an infant with "*serous*" *meningitis*, with raised cells and protein in the C.S.F., who lapsed into deep coma. Repeated lumbar puncture gave only a few drops of C.S.F. under no measurable pressure. Ventricular puncture showed a similar low C.S.F. pressure. Considerable improvement followed the intraventricular injection of 15 ml. of saline solution and the intravenous injection of saline solution and distilled water. A further lapse into coma associated with ventricular collapse was rapidly and completely cured by injecting 35 ml. of saline solution into the ventricles, with vigorous intravenous fluid therapy.

A case of acute *meningococcal meningitis* and one of *acute encephalitis* with coma were described by Thieffry et al. (1943). Both these cases showed evidence of cerebral hypotension and improved remarkably under appropriate treatment.

Puech et al. (1942b) reported a case showing mental depression, wasting, insomnia, and confusion followed by sudden coma. Cerebral hypotension was diagnosed, and trephine holes were made. The brain was found to have shrunk away from the dura, and ventricular pressure was low. Injection of serum and air into the ventricles produced a rapid recovery. The patient later relapsed into coma, with identical physical findings and a similar response to treatment. This was repeated three more times, the last coma being fatal eighteen months after the onset of his illness. At necropsy no macroscopic pathological process was seen, but histologically the choroid plexus showed gross sclerosis of the capillaries with hyaline degeneration. The epithelium showed no evidence of secretory activity. A possible pathological basis for the causation of spontaneous intracranial hypotension is suggested by this case.

The association of low C.S.F. pressure in cases of chronic *subdural hæmatoma* is well known. The ventricles are sometimes reinflated with air or with saline solution after evacuation of the blood-clot in this condition (Krebs et al. 1937).

Two cases of *intraventricular hæmorrhage* with hypotension cured by evacuation of the blood-clot and reinflation of the ventricles with air were described by Puech et al. (1935).

Two cases of *intracerebral hæmorrhage* with hypotension have been seen and successfully treated by evacuation of blood-clot and rehydration by Miss D. J. K. Beck (personal communication).

The apparently anomalous association of *cerebral œdema* and cerebral hypotension has been described by Puech et al. (1948), who also reported the case of a child developing diabetes insipidus, headaches, drowsiness, narcolepsy, and coma after an operation for a persistent urachus. The brain was sunken, gelatinous, and dehydrated, and the ventricular pressure was very low. Rapid cure followed reinflation of the ventricles.

A case of *sunstroke* in a child, with coma of several days' duration in which clinical and manometric evidence of intracranial hypotension was present, was described by Sorel et al. (1951). Rapid relief followed the intraventricular injection of 20 ml. of physiological saline solution. After a few hours intracranial hypertension supervened; this was rapidly relieved by the withdrawal of a few millilitres of C.S.F. through the trephine holes. This lability of the C.S.F. pressure has often been noted, and lends a note of caution about the introduction of fluid into the subarachnoid space.

Various *psychological syndromes* associated with intracranial hypotension have been reported: depression (Puech et al. 1942a); and maniacal and narcoleptic forms (Puech et al. 1942c). Acute hypotension as a cause of irreversible coma during insulin shock therapy has also been noted (Delay et al. 1948). Low C.S.F. pressures occur not infrequently in schizophrenia (S. Sherwood, personal communication).

CLINICAL PICTURE

The symptoms of cerebral hypotension are not specific and may equally be present in intracranial hypertension and other conditions They do not seem to be directly related to the degree of hypotension

Headache is the chief symptom Its occurrence after lumbar puncture is usually attributed to hypotension of the C S F

Jacobæus and Frumerie (1923) reported two cases, with severe headache following lumbar puncture, in which repeated puncture revealed a pressure of zero both cases responded immediately to raising of the C S F. pressure with intrathecal saline solution 35 ml and 90 ml.

Alpers (1925) found headache after lumbar puncture in sixteen out of ninety-one patients in whom 15–25 ml of C S F had been removed In all these cases the C S F pressure fell notably after removal of C S F Alpers suggested treatment with pituitary posterior-lobe extract for mild cases and intravenous hypotonic fluids in more severe cases, and recommended a small needle for the puncture and a period of recumbency after the puncture.

Pickering (1948), discussing 11 cases of reaction to lumbar puncture, described headache and pain in the occiput, neck, shoulders, and back, with or without neck stiffness The headache was worsened by sitting upright, by jugular pressure, and by shaking the head, and was lessened by lying down In all the cases repeat lumbar puncture showed a low pressure

Kunkle et al (1943) constantly induced headache by drainage of about 20 ml of C S F with the patient in the erect position The headache was reduced by tilting the patient towards the horizontal or by flexion or extension of the head, and was exacerbated by the erect position These postural changes were independent of estimated intravenous pressure Drainage headache was reduced in intensity by intrathecal injections of physiological saline solution and restoration of the volume of C S F These workers agreed with MacRobert (1918) that headache after lumbar puncture was due to a fall in C S F pressure as a result of prolonged leakage through the hole in the dura

The character of the headache in other conditions associated with a low C S F pressure is similar to that seen after lumbar puncture It may be mild or severe, frontal or, more often, occipital, spreading down the neck and back to the shoulders, is accentuated by the erect position and movement of the head, is relieved by lying down, and may be associated with various degrees of neck stiffness and a positive Kernig's sign

Vertigo often occurs with headache and is also worsened by changes of posture and movement of the head. With it may be seen various degrees of ataxia and disorders of equilibrium

Vomiting may occur, especially at the height of headache, and is often preceded by nausea, which may be present alone in milder cases Evidence of general dehydration can be seen after prolonged vomiting

Symptoms of diabetes insipidus and narcolepsy are sometimes present

Generalised epileptiform *convulsions* and jacksonian epilepsy have been described and are relieved by raising the C S F pressure Focal neurological signs—e g, hemiplegia and aphasia—may occur

Disorders of consciousness, ranging from apathy to deep coma, are common and, if untreated, may proceed to death

Disturbance of autonomic centres, with fever and alteration in pulse-rate and blood-pressure, may also be noted

Psychological changes have been mentioned above

ILLUSTRATIVE CASE-RECORDS

After Lumbar Puncture

Case 1.—A married woman, aged 27, was admitted to the neurological wards of this hospital, where early disseminated sclerosis and hysterical retention of urine were diagnosed For the previous month, after an emotional shock, the patient had not passed urine normally and had been catheterised once daily in the casualty department of another hospital During this time her fluid intake had been reduced to about a pint daily Shortly after admission a history from her

Lumbar puncture was done the day after admission, in the left lateral position A pressure of 50 mm H_2O was recorded After 7 ml *of C S F had been removed, the pressure* fell to zero The foot of the bed was raised on blocks Both before and after lumbar puncture the patient refused to take *adequate fluids* Shortly after the puncture she complained *to the nurses of* giddiness and a 'sense of oppression' in her head, *these diminished* during the evening Next morning *she had no* symptoms until her bed was taken down from blocks, when she again noticed giddiness and headache At 11 A M she asked for a bedpan, on to which she was helped by *a nurse* A few moments later she was found lying *unconscious in the bed*

On examination her respiration was slow and stertorous, *pulse rate 80*, and blood pressure 84/60 mm Hg She was deeply comatose and unresponsive to painful stimuli She had *pin point* unreacting pupils, normal optic fundi, and absent corneal reflexes Her limbs were hypotonic, deep reflexes absent, and plantar responses extensor

Diagnosis and treatment—Acute cerebral hypotension was diagnosed, but in view of the gravity of her condition no attempt was made to confirm this diagnosis by further lumbar puncture Her bed was placed on high blocks, and she was given three pints of intravenous physiological saline solution in an hour She responded to this treatment by suddenly becoming more conscious and moving her limbs spontaneously Her, pupils became widely dilated, her corneal and deep reflexes returned, and her plantar responses became feebly flexor

Progress—In the next few hours, during which the intravenous saline solution was injected slowly, her condition showed remarkable variation from deep coma with pin point pupils, absent corneal and deep reflexes, and bilateral extensor plantar responses, to violent semi-coma during which she flung herself about the bed and needed restraint and sedation her pupils were widely dilated, her corneal and deep reflexes were present, and her plantar responses were flexor These changes occurred with great rapidity, and it was noticeable that each period of violence was followed by sudden collapse into deep coma By 11 P M she was screaming and moaning hysterically, and she resisted actively any interference or attempted examination No abnormality apart from an apparent inability of lateral conjugate deviation of the eyes was detected Her blood pressure was 130/80 mm Hg, having slowly risen from its previous low level in the preceding twelve hours Next morning she was fully conscious, complaining of no symptoms, but was difficult, noisy, uncoöperative, and resistant to examination Her eventual recovery was complete, and her further stay in the neurological ward was characterised only by a hysterical anæsthesia of her left leg and a very hysterical gait She was discharged to the mental wards of the hospital for further treatment

Comments—This dramatic, and fortunately rare, reaction to lumbar puncture was due, in all probability, to a sudden fall in C S F pressure in a patient with a latent dehydration occasioned by a very deficient fluid intake in the month preceding lumbar puncture This diagnosis is supported by the low initial C S F pressure and its fall to zero after removal of a small amount of C S F for diagnostic purposes Although C S F pressure readings were not repeated, owing to the gravity of her condition, it is a reasonable presumption (in view of her history and her recovery with rehydration) that her symptoms were due to sudden intracranial hypotension The immediate cause of her collapse was undoubtedly the adoption of the erect position with its attendant lowering of intracranial pressure Such an event must indeed be most unusual, but it is perhaps expedient that the possibility of collapse and even death may be known to occur in certain special circumstances following lumbar puncture

In Association with Subdural Hæmatoma

Case 2—A married woman, aged 55, sustained a very mild blow on the head while getting into a car on Aug 22, 1948 A week later she complained of sudden onset of vertical and occipital headache She gradually became drowsy, and for eighteen hours was stuporose She vomited twice during this time Recovery from the incident was rapid, but com adache persisted for a week. She then again became uporose, and on admission was in semi-coma.

On examination her temperature was 99·8°F, pulse-rate 70, espirations 26 a minute. She was incontinent of urine and esponded slowly to painful stimuli. Her right pupil was arger than her left and moderately dilated. Evidence of a eft hemiplegia was present, but both plantar responses were xtensor. She had mild neck stiffness.

Lumbar puncture showed clear C.S.F. under a pressure of 0 mm. H_2O and containing protein 40 mg. per 100 ml., ed cells 17 per c.mm., and lymphocytes 15 per c.mm. A subdural hæmatoma was diagnosed.

Treatment and progress.—On Aug. 5, 1948, bilateral exploratory posterior parietal burr-holes were made. When the dura on the left side was opened, dark altered blood gushed out, and the brain was found to be depressed 7 mm. below the surface of the dura. The blood was sucked out and saline solution run through until clear. About 30 ml. of blood was removed. On the evening of the operation the patient became conscious, spoke rationally to relations, and complained of headache. She was again drowsy next morning and later stuporose. Her pupils were small but equal, and the signs of hemiplegia remained unchanged. Radiography of the skull showed considerable recession of the brain from the front of the skull in the face-up position. In view of the possible reaccumulation of fluid or of blood the patient was re-explored. No evidence of fresh subdural hæmorrhage was found, but the brain had shrunk from the dura on both sides of the skull. The intraventricular pressures were not measured. Intracranial hypotension was diagnosed, the patient was nursed in the head-down position, she was given plenty of fluids, and an intravenous drip of physiological saline solution was set up. The patient gradually improved and within three days had returned to normal consciousness, her hemiplegic signs disappearing by the seventh day. She was discharged entirely normal at the end of a month.

Comments.—The initial C.S.F. pressure in case 2 was low (30 mm. H_2O), a finding which is well known to accompany chronic subdural hæmatoma. The patient's partial recovery after operation is consistent with the removal of 30 ml. of subdural blood, and her relapse into semi-coma with evidence of cerebral dehydration strongly suggests intracranial hypotension. Her recovery with rehydration confirms this impression.

Spontaneous

Case 3.—A female clerk, aged 38, had had a duodenal ulcer diagnosed in 1945. She had been treated medically until 1947, when a vagotomy was done, since when she had had no further dyspepsia. After vagotomy she had remained in hospital for three weeks and then been sent to a convalescent home. On the third day, while looking in a shop window, she had felt a sudden shooting pain through the front of her head. This was followed by unconsciousness lasting $1^1/_2$ hours. The attack was described as "unlike an ordinary faint," because she bit her tongue and went stiff. She felt dazed and muzzy in the head for three days. Some weeks later she began to experience muzzy heavy headaches, later increasing in severity and frequency until she was admitted to hospital in June, 1949, for investigation. In July, 1948, during a twenty-mile bus ride she noticed a thumping muddled headache with dizziness. On leaving the bus she fainted; she awoke in hospital, feeling weak and dazed, and with a frontal headache. She was discharged the same day. In May, 1949, after a worrying day she had had a similar headache and again lost consciousness while leaving a bus. She bit her tongue, foamed at the mouth, passed her urine, and went stiff. She was unconscious for two hours. Headache remained severe after this attack, and she lost consciousness twice two days later. Hypoglycæmic attacks had been tentatively diagnosed before her first admission in June, 1949.

Physical examination showed no abnormality. A glucose-tolerance test, an insulin-glucose-tolerance test, electrocardiography, electro-encephalography, lumbar puncture, radiography of the skull, a blood-count, a Wassermann reaction of the blood, and liver-function tests were normal, but the C.S.F. was under a low normal pressure of 60 mm. H_2O. Hypoglycæmic attacks, induced with intravenous insulin, bore no resemblance to her usual attacks. No certain diagnosis was made, and the patient was discharged.

Readmission.—Her symptoms gradually increased in severity, necessitating readmission in March, 1950. A more detailed history of her headaches revealed certain important characteristics. The headache was mainly frontal in distribution but travelled to the occiput and back of the neck when severe. The severity varied from a mild muzzy heavy feeling to severe incapacitating pain with stiffness of her neck, photophobia, vertigo and nausea, but no vomiting. The pain was sometimes much exacerbated by coughing, sneezing, straining, jolting, turning the head quickly, and noise. The headache never occurred at night and usually started shortly after the patient got up in the morning. When the pain was severe, the patient felt the need to lie down, which act consistently relieved the pain within a few minutes. She noticed that aspirin hastened the relief of pain if she lay down, but alone, or combined with rest in the upright position in a chair, it had no effect. A recumbent position therefore appeared necessary for relief. After a headache the patient felt weak, dazed, and shaky. In association with headache she was often giddy, with objects rotating in an anti-clockwise direction. This symptom was also rapidly relieved by lying down. Apart from a mild but definite loss of concentration she had no other symptoms. She admitted to being slightly highly strung but did not relate her symptoms to periods of stress and anxiety, and she showed no apparent evidence of emotional instability.

Physical examination was entirely negative, and in view of the characteristics of her headache a diagnosis of intracranial hypotension was considered.

Lumbar puncture was done without difficulty. The C.S.F. pressure was 30 mm. H_2O, rising rapidly on jugular pressure to 120 mm. H_2O and falling equally rapidly to its former pressure; 7 ml. of C.S.F. was removed for examination, and after its removal the spontaneous flow of C.S.F. ceased. The C.S.F. was normal in constitution.

Treatment and progress.—The foot of the patient's bed was placed on blocks, but the same evening she developed headache, which was greatly increased next morning, when the blocks were removed. The headache was similar to her usual headache, was frontal and occipital in distribution, extending down the back of the neck, which felt stiff, to her shoulders. The bones of her neck were tender, and she had photophobia, vertigo, and increased headache on raising her shoulders from the bed. The headache was much increased by shaking her head, coughing, and, to a less extent, by jugular compression. Her neck showed slight stiffness and was painful on movement. The foot of the bed was again raised, the patient was given as much fluids as she would take, and after four days her symptoms had entirely disappeared. This reaction was that of a typical moderately severe post-lumbar-puncture syndrome, but the resemblance between these symptoms and those for which she was admitted was striking. Two attempts were made to induce symptoms by lowering intracranial pressure with 50% intravenous sucrose (50 ml. and 75 ml.) but without success. The patient next induced an attack by spending the day among the noise and bustle of London traffic. She returned with moderately severe headache. Two hours later lumbar puncture produced C.S.F. under a pressure of 35 mm. H_2O. Entirely without the patient's knowledge 20 ml. of physiological saline solution was introduced into the spinal theca, raising the C.S.F. pressure to 100 mm. H_2O. After 12 ml. had been injected she said that the headache had completely disappeared. Eight hours later headache returned with considerable severity combined with nausea and giddiness. After the ingestion of 750 ml. of water and an intramuscular injection of 10 units of 'Pitressin' considerable improvement took place for three hours. After diuresis the headache returned. In view of the effect of oxygen in raising intracranial tension under certain conditions the patient was treated in an oxygen tent with a flow of 6 litres a minute for two hours, with almost complete relief of symptoms. She was discharged symptom-free a week later. When she resumed work her symptoms recurred, and fluids and salt in large amounts, pitressin snuff, ephedrine, *d*-amphetamine sulphate, and sedatives have been used without effect.

Comments.—The unusual characteristics of this patient's headaches first drew attention to the possibility of intracranial hypotension as a cause. The low C.S.F. pressure and the rapid relief obtained by raising this pressure are strong evidence that this presumption was correct.

After Torkildsen's Operation for Hydrocephalus

Case 4.—A schoolgirl, aged 15, had hydrocephalus. Preoperative ventriculography revealed gross hydrocephalus, probably due to stenosis of the aqueduct, since the fourth ventricle and the aqueduct of Sylvius were not filled. Ventricular pressures of 20 mm. H_2O were recorded. Ventriculography was followed by Torkildsen's operation, a ventriculo cisternostomy.

Postoperatively the patient's condition remained excellent for the next two days. At lumbar puncture the C.S.F. pressures on these days were 210 mm. and 240 mm. H_2O, and 20 ml. and 30 ml. of C.S.F. were withdrawn. On the third postoperative day the child's condition began to deteriorate, and she complained of severe headache; the C.S.F. pressure had fallen to 60 mm. H_2O. Next day she was worse, being drowsy and responding with difficulty to questions. Her headache remained severe; she was incontinent of urine, and her pulse-rate had slowed to 60. Her pupils were large, eccentric, and sluggish in reaction; a divergent squint was present. A combined ventricular and lumbar puncture was done. The lumbar pressure remained at 60 mm. H_2O, but no ventricular pressure was recordable. The child was now nearly comatose. An intravenous drip of physiological saline solution was started, two pints being given rapidly, and then continued more slowly. For the first four hours after the drip began the patient remained comatose, with dilated unresponsive pupils, a divergent squint, flaccid extremities, a low blood pressure, a rising irregular pulse rate, slow irregular respiration, and slight cyanosis. After six hours voluntary movement to command began to return. Hypotonic saline solution and, later, distilled water were substituted for physiological saline solution. By twelve hours she was complaining of an "awful headache" and could answer simple questions and move her limbs voluntarily. After twenty-four hours she was fully conscious and had no headache or abnormal neurological signs apart from those that existed before operation. By this time she had been given eight and a half pints of intravenous fluid. Her further convalescence was uneventful.

Comments.—This girl's condition on the fourth postoperative day was so serious that it was thought she would die. Within twenty-four hours she had returned almost to normal through vigorous rehydration, showing the remarkable and gratifying response to early treatment in intracranial hypotension. Since this complication may occasionally follow the Torkildsen procedure it should be suspected whenever alterations of consciousness, pulse-rate, respirations, temperature, or blood-pressure appear, with or without evidence of meningeal irritation or focal neurological abnormality.

PATHOGENESIS

Various mechanisms may play a part in the production of intracranial hypotension; these mechanisms resolve themselves largely into the following three main groups.

(1) *Excessive loss of C.S.F.* may follow compound fractures of the skull, intracranial operations with leakage of C.S.F., and, occasionally, prolonged dural leakage after lumbar puncture or spinal anæsthesia.

(2) *Insufficient production of C.S.F.*—Under normal conditions C.S.F. is produced by the choroid plexuses, circulates throughout the subarachnoid space, and is absorbed into the arachnoid villi. Its formation within the choroid plexus depends on active secretion by these cells and not on simple filtration (Flexner 1934). This process may therefore be affected by alterations in the nervous control of, or blood flow through, the plexus or by degenerative changes within the plexus. After head injuries spasm of cerebral blood-vessels may occur in man and be seen experimentally in animals. A sudden fall of blood pressure, or peripheral vascular failure with consequent diminution of blood flow through the choroid plexus, may lead to diminished formation of C.S.F. Dehydration may have a similar effect. Severe toxæmia may affect either the cerebral blood flow or the secretory cells of the choroid plexus. Degenerative changes in the plexus may occasionally lead to a chronic and progressive diminution of production of C.S.F., as in the case described by Puech et al. (1942b).

(3) *Increase in size of subarachnoid space*.—A relative insufficiency of C.S.F. can be the result of an increase in the capacity of the subarachnoid space due to cortical atrophy such as follows head injuries and cerebrovascular accidents, or of the removal of the space-occupying lesions within the skull. The first mechanism may be present in chronic cases but is otherwise unlikely to be of importance.

Cause and effect are clear in groups 1 and 3, but much remains to be learnt about the factors operating in group 2. It is tempting to incriminate disturbances of the hypothalamus as the cause of diminished production of C.S.F. and of certain symptoms of intracranial hypotension. Changes in consciousness seen in intracranial hypotension may resemble the "arrested consciousness" sometimes observed in hypothalamic lesions, and alterations in temperature control, blood-pressure, and pulse rate may indicate dysfunction of vegetative centres. Chorobski (1950) believes that a centre may exist in the diencephalon for the production of C.S.F., which can be affected, through alterations in cerebral blood flow, by (1) simple exposure of the brain to the atmosphere, (2) the effect of afferent nerve impulses from the operation site, and (3) tissue metabolites released from the area of trauma. It seems equally possible, however, that any disturbance of the hypothalamus which occurs may be the result, and not the cause, of the hypotension, both, perhaps, being produced by diminished cerebral blood-flow. Russell (1948) also considered the possibility of a hypothalamic disorder, but through its action on general body-water control. Ryder et al. (1952) have produced evidence, by estimation of cerebral blood-flow and C.S.F. pressure in man, that variations in cerebral blood-flow induce changes in C.S.F. pressure in the same direction. They have also shown that changes in cerebral blood-flow and in the arterial and jugular venous pressures may be completely dissociated, and that, when C.S.F. pressure varies concomitantly with changes in systemic arterial pressure, it is because the cerebral blood-flow varies concomitantly with the changes in systemic arterial pressure. These findings strongly support the view that diminished cerebral blood-flow may be of the greatest importance in the causation of intracranial hypotension.

TREATMENT

Pressure within the subarachnoid space may be increased either by the introduction of fluid or of air directly into the space, by increasing the production of C.S.F., or by retaining fluid within the body.

Lumbar-puncture reactions usually respond satisfactorily to nursing with the foot of the bed raised and forced fluids. As suggested by Alpers (1925) pituitary posterior-lobe extracts may be used to inhibit diuresis. Possibly a large intake of fluids and sodium before lumbar puncture may lessen the likelihood of reactions.

In acute cases of intracranial hypotension more drastic measures are indicated. Intravenous injection of 20–40 ml. of distilled water was successfully used by Leriche and should be tried first. Hypotonic solutions increase the production of C.S.F. (Weed and Hughson 1921), and the danger of hæmolysis is minimal with this dosage. Intravenous infusion of hypotonic or of physiological saline solution, or of plasma is also effective, but its action is slower. Pressure within the theca may be rapidly raised by the introduction of either physiological fluid or air into the subarachnoid space or into the ventricle. We have been able largely to abolish lumbar-puncture reactions after the removal of 30 ml. of C.S.F. in a few cases of disseminated sclerosis, in which reactions are common, by the immediate introduction of physiological saline solution. Only 20–25 ml. of physiological saline solution is needed to restore the original pressure, which fact suggests that a reactive increase in the production of C.S.F. has taken place. This method of treating intracranial hypotension is easy and satisfactory, but the strictest aseptic precautions must be taken. There is also the disadvantage that further C.S.F. may leak through the hole in the dura and cause the gradual return of symptoms. The use of air in reinflation of the ventricles (" regonflage du cerveau " or " pneumothérapie cérébrale ") is widely recommended by Delay and Sizaret (1947), partly because of its action of re-establishing intraventricular pressure and partly because of its "irritant" effect on the choroid plexus. Since some French workers insist that direct measurement of the intraventricular pressure is essential in the diagnosis of intracranial hypotension they recommend the introduction of air into the ventricles through a needle passed through the trephine holes. The lumbar route may also be used. The value of reinflation of the ventricles with air has a diagnostic, in addition to a therapeutic, value because radiography of the skull after this procedure may reveal some unsuspected focal abnormality.

For less acute cases other measures may be taken. Many drugs—e.g., adrenaline, ephedrine, d-amphetamine sulphate, and pilocarpine—are thought to increase C.S.F. pressure. None of these exerts much therapeutic effect. The inhalation of oxygen causes a large increase in C.S.F. pressure in patients with emphysema and cor pulmonale, due to carbon dioxide retention, and oxygen has also been used to relieve symptoms following air encephalography. Although there is no evidence that oxygen can cause an increased C.S.F. pressure in normal people, it was tried with success in case 3 and might prove a valuable therapeutic measure in other cases.

In chronic idiopathic intracranial hypotension such measures are either impracticable or valueless, and for these cases certain radical surgical measures have been suggested—e.g., ligature of the inferior longitudinal sinus or of the internal jugular vein, and pericarotid sympathectomy. Until we know more about intracranial hydrodynamics, these procedures can only be considered as experimental. Early diagnosis is essential, when appropriate therapy may be effective, because some cases progress to irreversible intracranial hypotension and death.

SUMMARY

The history, clinical picture, ætiology, pathogenesis, and treatment of intracranial hypotension are discussed.

Clinicians should be aware of the occurrence of intracranial hypotension as a complication in certain cases of head injury, infective or vascular intracranial conditions, and following lumbar puncture, spinal anæsthesia, and cranial operations.

Intracranial hypotension is diagnosed from a combination of certain non-specific symptoms and signs in association with a low C.S.F. pressure, and its significance must remain uncertain until we know more about intracranial hydrodynamics.

I wish to thank Miss D. J. Kinloch Beck, Prof. A. Kekwick, and Dr. D. McAlpine for permission to publish these cases.

RECOGNITION OF PRIMARY TUBERCULOUS INFECTION OF SKIN AND MUCOSÆ

F. J. W. MILLER
M.D. Durh., M.R.C.P., D.C.H.
ASSISTANT PHYSICIAN, CHILDREN'S DEPARTMENT, ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON TYNE

With illustrations on plate

WHEN Ghon (1912) described the anatomical and pathological characteristics of the primary tuberculous infection in childhood he recognised that the primary focus with enlargement of regional lymph-nodes could be in the skin or on any mucosa as well as in the lungs or abdomen. From that time onwards a constant trickle of cases has been published of primary complexes situated in almost every part of the human body. Nearly always, however, these reports are of one or two cases, and the inference is drawn that primary infection in sites other than lung and abdomen is curious and interesting but uncommon. Indeed I have found only one published report of more than 6 cases: Stokes (1925) reported 10 from the Mayo Clinic. He made the point which is the object of the present paper:

> "A better acquaintance with the clinical characteristics of this lesion would result in the identification of more cases, especially by those who as surgeons, internists, pediatricians, and roentgenologists are required to deal with the superficial tuberculous adenopathies."

Because I believe that this statement is true, and that primary tuberculous infection of the skin and mucosæ is often unrecognised, I describe and illustrate here the characteristics of primary infection of the skin and of the mucosæ of the mouth and the conjunctiva in 28 patients.

PRIMARY LESION OF TUBERCULOSIS

The recognition of a primary infection of tuberculosis in a child, adolescent, or adult is possible because the body reacts to an initial infection with tubercle bacilli in a unique recognisable way. Wherever the site of infection may be, the reaction is the same; some bacilli remain to form a small local lesion, while others pass rapidly along lymphatics to the nearest node, which enlarges and, from about two to four weeks later, caseates. As caseation occurs, the body becomes sensitive to tuberculo-protein. This altered sensitivity has a profound influence on the body's reaction to any subsequent infection; for, if that takes place, there is a local reaction of variable severity, but the regional lymph-nodes do not caseate. This type of lesion was previously seen on the skin as the " butchers' wart " or on mucosa as the shallow painful tuberculous ulcer of lip or mouth in persons with phthisis. But wherever the combination of a tuberculous lesion with caseous tuberculosis of the regional lymphatic glands can be demonstrated, we have strong presumptive evidence that the patient is undergoing his primary infection. If we have also observed tuberculin conversion, the presumption becomes certainty. It is apparent, however, that this will be uncommon under ordinary conditions of clinical study, and all but 2 of my patients were tuberculin-positive when first seen Simultaneous infection at different sites (e g, lung and skin) or further infection before sensitivity has developed will produce the same reaction of the primary complex—a focus and regional adenitis at each site of infection

GENERAL FEATURES OF CASES

My study of this condition began early in 1947, when I saw 2 children

(1) An infant, aged six months, was brought for routine examination to the Contact Clinic in Newcastle Her mother was dying of phthisis, and the child had a primary complex in the lung, but since the age of six weeks she had also had an indolent ulcer on her chin and a submental swelling which at first had been hard but had softened and was discharging The ulcer, set in the skin without surrounding inflammation, was small and circular, with two nodules of "apple jelly" material in its rather elevated edge We could not obtain permission for biopsy, but both the skin lesion and the regional gland, after a further abscess in the neck, healed slowly, with subsequent calcification at the sites of the gland abscesses

(2) I saw the second child shortly afterwards, when she was four months old Her father had phthisis, but she was well and was tuberculin negative Two months later she was seen by a colleague in a child-welfare centre She was still well but had developed a small hard papule on the face and a firm swollen gland at the angle of the jaw, and her tuberculin reaction was positive In this child we watched the slow evolution of the lesion without biopsy which would have destroyed its appearance Fig 1 shows the second child six months after the lesion was first seen, fig 2 the development of satellite nodules (see below), and fig 3 shows the lesion after natural healing was complete twelve months later

With interest stimulated I undertook a wider search and more systematic investigation, and in the five years to February, 1952, with the help of friends in the children's, surgical, ophthalmological, and dental departments of the Royal Victoria Infirmary, I have been able to record, photograph, and study 28 examples of primary infection of the skin, mouth, or eye This number excludes 9 other cases of which I possess notes and in some instances photographs, but which I have not been able to see often enough to make a sufficiently detailed and prolonged study

With 1 exception, a farm labourer aged nineteen, the patients were all children aged less than twelve years In 20 cases the primary infection was situated on the skin, in 5 on the conjunctiva, and in the remaining 3 the mouth All the children with infections of skin or mouth lived in the industrial areas along Tyneside in North-eastern England, whereas 3 of the 5 children with infection in the eye lived in the country areas, of them on farms The ages and salient facts of the cases are given in the accompanying table, which shows that in 22 of the 28 cases we were able to prove the tuberculous nature of the primary focus The 6 exceptions include the child who had been examined when tuberculin-negative and we did not wish to disturb the evolution of the lesion, a child with the primary lesion on the sole of the foot, where biopsy was considered inadvisable because a painful scar might remain, though tubercle bacilli were recovered from the inguinal glands, and 4 others where we could not obtain a biopsy for other reasons In 2 of these 6 patients additional information supporting the diagnosis of tuberculosis has been the observation of a change in the tuberculin reaction, in 2 others the appearance of erythema nodosum at the expected time, and the calcification in the regional glands which has appeared in every case These factors, together with the clinical course of the illness, leave no reasonable doubt that all the cases included in this series are examples of primary tuberculous infection

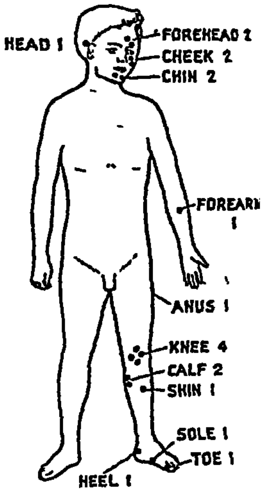

Fig 4—Anatomical distribution of 19 primary tuberculous lesions of skin

PRIMARY LESIONS IN SKIN

There were *20 such cases* In 3 the children were aged less than one year when the lesion first appeared 2 were in the second year, 8 were between two and five years old, and the eldest of the remaining 7 was nearly eleven years old All but 1 of the lesions were

SYNOPSIS OF DATA OF 28 CASES OF PRIMARY TUBERCULOUS INFECTION

Case no	Age at onset (yr)	Site	Contact	Trauma	Primary focus histology	Regional gland		First symptom
						Calcification	Histology or bacteriology	
1	$3^{2}/_{12}$	Shin	Mother	No	+	+	+	Swelling in groin
2	$2^{4}/_{12}$	Cheek	None	Yes	+	+	+	Spot on face, and swelling in front of ear
3	4	Knee	Mother	No	+	+	+	Acute inguinal adenitis
4	7	Heel	None	Yes	+	+	+	Inguinal adenitis and lack of healing
5	$5^{10}/_{12}$	Knee	None	No	+	+	+	Inguinal swelling
6	8	Foot	None	Severe injury	−	+	+	Lack of healing after accident
7	$1^{10}/_{12}$	Arm	Father	No	+	+	+	Axillary adenitis
8	8	Toe	None	Yes	+	+	+	Swelling in groin
9	$^{4}/_{12}$	Knee	Mother	No	+	+	+	Red area on knee
10	$2^{9}/_{12}$	Calf	Uncle	No	+	+	+	Acute inguinal adenitis
11	$3^{6}/_{12}$	Knee	Father	Yes	+	+	+	Scab did not heal
12	$10^{9}/_{12}$	Chin	None	Yes	+	−	+	Swelling under chin
13	$1^{8}/_{12}$	Anus	Father	Yes	+	+	+	Swelling in groin
14	$^{6}/_{12}$	Chin	Mother	No	−	+	−	Lesion on chin, submental abscess
15	$^{8}/_{12}$	Cheek	Father	No	−	+	−	Spot on face, tonsillar gland swelling
16	$2^{7}/_{12}$	Forehead	Aunt	Yes	−	+	−	Wound did not heal
17	$4^{6}/_{12}$	Forehead	Aunt	No	−	+	+	Scab on forehead, and abscess in front of ear
18	$6^{9}/_{12}$	Head	None	Severe injury	−	+	+	Postauricular abscess
19	4	Calf	None	No	Tubercle bacilli isolated	−	+	Ill on admission after measles
20	$3^{6}/_{12}$	Foot	None	Yes	−	+	+	Septic foot and acute adenitis
21	9	Eye	None	?	+	−	+	Sore eye
22	$11^{9}/_{12}$	Eye	None	No	+	+	+	Swelling of tonsillar gland
23	$10^{9}/_{12}$	Eye	None	?	Tubercle bacilli isolated	+	+	Chronic conjunctivitis
24	10	Eye	None	?	−	+	+	Irritability of eye
25	$^{9}/_{12}$	Eye	Aunt	No	Tubercle bacilli isolated	+	+	Small swelling in front of ear
26	$7^{10}/_{12}$	Mouth	None	No	+	+	+	Ulcer in mouth
27	$8^{9}/_{12}$	Mouth	None	Yes	+	−	+	Submaxillary swelling
28	2	Mouth	None	Yes	+	+	+	Submaxillary swelling

found on skin surfaces exposed to injury and to contamination from outside dust and dirt. This distribution about the face and the legs below the knee can be seen in fig. 4: 7 lesions were on the face and head; 11 on the knee, lower leg, and foot; 1 on the forearm, and 1 at the anus. In one child (case 6, not illustrated in fig. 4), the whole of the foot was involved in the primary infection. In 11 of the 20 children there was known contact with an infective adult, either a member of the family or a frequent visitor. In 10 cases there was a history of trauma, including 2 major injuries from road accidents. Yet only in 3 cases were both injury and contact combined and only 2 were without either; nor was there evidence of trauma in one area and contact in another, an equal division of each between face and leg being seen.

Thus the presence of either contact or trauma is important, but it is unusual to get a history of both, and I do not know if slight injury is always necessary before a primary infection can be established. Yet it might be reasonable to think that, where there is a frequent contact with an infective adult, the chance of infection of a minute skin lesion is fairly high, whereas with larger cuts or injuries the possibility of dust infection, presumably with small numbers of tubercle bacilli, increases.

PRESENTING SYMPTOMS

Only 1 child presented with a systemic illness, pyrexia following measles, later becoming miliary tuberculosis. In all the 19 others the mother found a local lesion when her child was otherwise well: in 6 it was a spot or a scab in the skin or a small wound or abrasion which did not heal; in 13 a swelling of a lymph-node in the groin, in front of the ear, or in the neck first gave rise to complaint and raised suspicion of tuberculosis. This lymph-node swelling in 10 cases was slow and painless, but in 3 the reaction was much more acute, 1 presenting with high pyrexia, great pain, and tenderness, and the other 2 with moderate tenderness, sufficient nevertheless to simulate a "septic" infection.

I do not yet know whether the acute type of reaction with rapid softening indicates the presence of a simultaneous infection with tubercle bacilli and pyococcal organisms, but the circumstances of infection are such that this is at least possible; it might also, however, indicate a severe reaction to tuberculous infection only. This point remains to be studied later.

Attention may therefore be directed to the primary infection in three ways:

(1) Reference may be made to a papule, a scab, or a small wound which does not heal.

(2) A painless glandular swelling may be found in the groin, axilla, neck, or in front of the ear.

(3) Occasionally the presenting symptom is a more acute type of glandular reaction, simulating an acute pyococcal infection.

CHARACTERISTICS OF PRIMARY FOCUS IN SKIN

The 20 cases comprised lesions in all stages of development: the earliest had been present only three weeks when first seen (and was not photographed for some time later), and others at least eighteen months when first seen. The natural course of healing was often interrupted, sometimes by surgical intervention for biopsy; others were healed by streptomycin therapy. I have not, therefore, found it possible to describe the evolution and healing of a "typical" lesion, and indeed, if it had been easily possible to do so, the appearance would have been well known long ago. The first characteristic is therefore variability; and, since the most significant factors in determining the shape and size of the primary focus are undoubtedly the presence and the type of visible injury into which the bacilli have been introduced, the natural division, for purposes of description, is into those cases with or without a history of trauma.

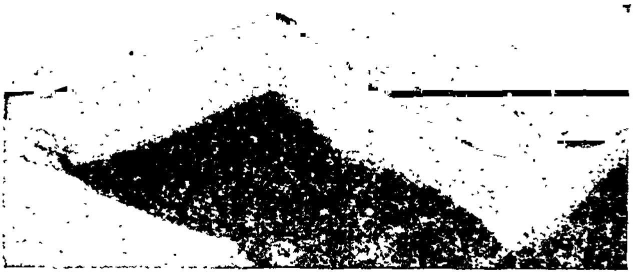

Fig. 5—Primary tuberculous lesion of skin of left foot, with painless enlarged lymph-node in left groin, in a boy, aged 7 years, eight weeks after he had cut his foot.

Primary Infection of Skin Following Injury

Of the 20 skin cases 10 had a history of injury, varying from a scratch by a puppy to a serious road accident. The wound at first seemed to heal but unexpectedly broke down about the end of the first week. The two road accidents were both major injuries: in the first, a compound dislocation of the ankle did not heal, the whole foot became a large tuberculous lesion, and a tuberculous abscess appeared in the groin; in the second, the boy was admitted to hospital with multiple injuries, including a large scalp wound. His tuberculin skin reaction was negative on admission, and he made a good recovery except for a ragged granulating area behind the right ear and a postauricular gland abscess from which tubercle bacilli were recovered. These two infections may have been from one of several sources: from tubercle bacilli in the road dust, by contact infection on the way to hospital, or within the hospital wards. All but 1 of the remaining lesions were in smaller cuts or abrasions and presented as small ulcers or scabs which had refused to heal for several weeks yet had remained without pain or surrounding inflammation and with slight, if any, discharge. The one exception was a boy who cut his foot on a piece of glass and within a few days had a painful lesion on the sole of the foot, with rapid swelling and extreme tenderness of the regional glands. Probably there were coincident tuberculous and pyococcal infections.

I shall give the history of 1 other child in rather more detail:

In July, 1949, a healthy lively boy, aged seven years, was paddling in a pool in a public park, when he cut the inner side of his left heel on a piece of glass, making a wound about 1 in. long. When he came home, his mother dressed it, and for the first week healing seemed satisfactory; by the end of the second week, however, it had broken down, forming an indolent painless ulcer. A month later, while bathing him, his mother found a painless swelling in his left groin. Within another fortnight this had become red, and he was then referred to hospital, where an abscess was incised. Like the wound on the foot, the incision did not heal, and another small incision was necessary. On this occasion tubercle bacilli were found in the pus, and I was asked to see the child. Biopsy of the lesion on the foot showed *tuberculous granulation* tissue, and the appearance of the primary complex at the time of the diagnosis, eight weeks after the onset, is shown in figs. 5 and 6.

When a wound is infected with tubercle bacilli, the appearance of the primary lesion is determined by the size and shape of the original injury. The clue to diagnosis is to suspect any wound which has broken down after initial healing and is accompanied by a painless enlargement of regional lymph-nodes.

Primary Lesions without History of Injury

Turning for comparison to the 10 other primary skin infections, without a history of trauma but mostly with a history of contact, we find the lesions are much less conspicuous and have not the same ulcerous appearance. Rather do they give the impression that, after the bacilli have gained entry, most of the activity takes place below the surface of the epidermis The distribution is still on exposed areas, the face and the leg below the knee Most of the lesions are $^1/_2$–1 in in diameter roughly circular or ovoid, with a depressed centre and a raised edge, and are set in the skin just below the epidermis Over the surface, especially in the centre of the focus, there are usually adherent silvery epidermal scales, while on close inspection of the edge or on pressure with a glass slide small "apple-jelly" nodules, similar to those seen in lupus vulgaris, can be observed The whole lesion looks innocent and indolent, it often passes unseen or is described as a "healed or healing septic spot" (figs 7 and 8) Only closer inspection and histological examination reveal its true nature In 1 case the primary focus did merit its first description of impetigo and indeed one wondered if an impetiginous area had not become infected with tubercle bacilli

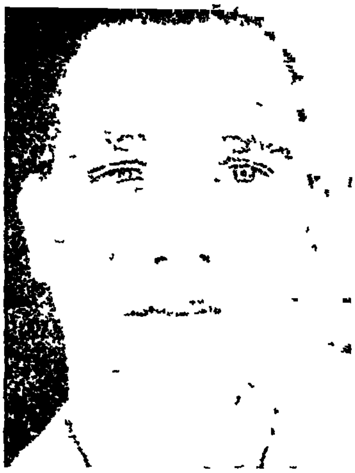

Fig 10—Œdema of right eyelid and swollen preauricular gland in youth aged 19

A boy, aged seven years, was seen in a children's sanatorium with a large fluctuating swelling in the right iliac fossa and the scar of a recently healed tuberculous sinus below the right inguinal ligament Further search revealed a circular lesion with a depressed centre and a raised edge in the skin over the patella (fig 9) So far as I could discover, this had never ulcerated, and no complaint had ever been made about it Histologically it was tuberculous, and eventually the large abscess in the right iliac fossa was opened, and caseous material obtained

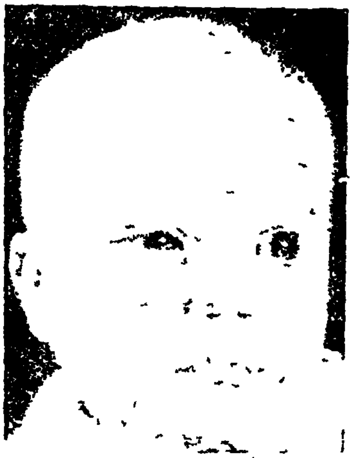

Fig 12—Œdema of eyelid on same side as swollen preauricular gland in boy aged 9 months

Several cases presented a phenomenon which may be peculiar to primary tuberculous lesions This was the development of scattered small nodules in the skin in a zone about the main lesion In 1 such case there was a history of trauma and the nodules disappeared as the lesion healed under streptomycin therapy In another case the primary focus healed naturally, leaving a serpiginous scar and small clear cut craters (fig 3) where the nodules (fig 2) had been In neither of these cases was a nodule removed for biopsy but in a 3rd case where the toe had previously been amputated, careful search at the base of the operation scar revealed a similar small lesion, which was removed and found to consist of tuberculous tissue The presumption is, therefore, that these nodules are tiny tuberculous foci, but we do not know how they arise, they might be examples of direct implantation from an explosive cough with bacilli laden sputum, or they might result from lymphatic spread from the primary focus, but, if so, I would have expected them

The examples described and illustrated here are enough to demonstrate the wide variety of forms of the primary infection Tuberculosis should certainly be suspected whenever a wound does not heal but does not show much inflammation The primary lesion without history of injury is more deeply set in the skin and often inconspicuous In 19 of 20 cases the primary lesion was painless, in the other secondary infection with pyococcal organisms was likely Indeed, whenever a tuberculous lymphadenitis is seen in groin, axilla or neck careful search should be made in the area drained by the gland, and any small nodules or ulcers should be closely examined

PRIMARY LESIONS IN EYE

Lesions on the conjunctiva were seen in 5 cases in the same period in 3 children aged between nine and twelve years, in 1 aged eight months, and in a youth aged nineteen Only the baby had a definite story of contact, 3 had a history of irritation of the eye, said to be due to a fly, exposure to artificial fertilisers, and dust and chaff at threshing-time, but there was no definite story of trauma Whereas all the 20 children with skin lesions lived in towns, 3 of these 5 lived in the country, 2 on farms Unfortunately I do not know if the organisms were human or bovine types of tubercle bacilli

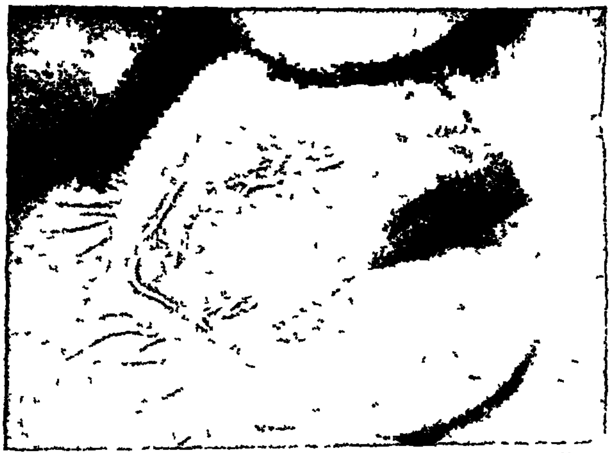

Fig 13—Shallow ulcer under eyelid in same case as in fig 12.

Three complained first of irritation in the eyes, and all 3 had enlargement of the preauricular gland, in the small infant the mother discovered a preauricular gland accidentally while washing the child, the remaining child attended outpatients with erythema nodosum and

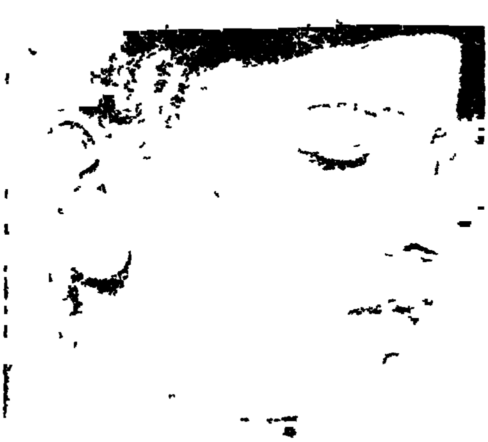

Fig 14—Swollen right submandibular gland in boy with ulcer on gum

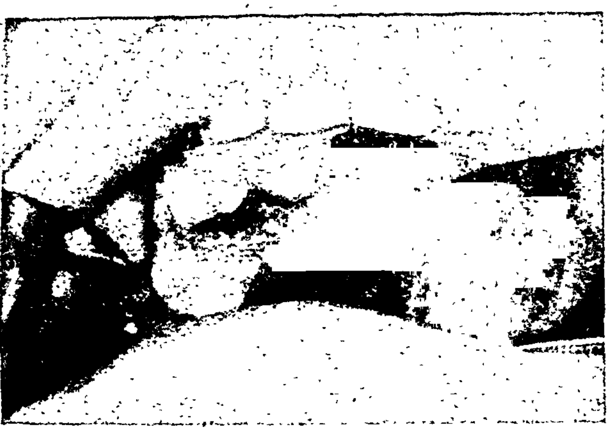

Fig. 15—Circular tuberculous ulcer of gum of right upper jaw in same case as in fig. 14.

a swollen tonsillar gland. Only in 1 case was the primary lesion easily visible as a mass of granulation tissue on the scleral conjunctiva towards the medial canthus; the 4 other lesions were all under the upper lid, but each could have been suspected by the presence of œdema of the eyelid on the same side as the glandular swelling (figs. 10 and 12). When the lids were turned up, the change revealed was uniformly greater than expected, either a fungating mass of granulations (fig. 11) or, as in the infant, a shallow ulcer with a yellow base and much surrounding œdema (fig. 13).

Painless preauricular lymphadenitis should always raise the suspicion of tuberculosis. If there is any complaint about the eyes, or if there is swelling of an eyelid, eversion, if necessary under anæsthesia, should disclose the primary focus. Even in the routine examination of children with cervical adenitis a quick look at the eyelids may be profitable.

A child, aged nine months, was born healthy, the only infant of artisan parents. At the end of April, 1950, while his mother was washing his face she found a small lump in front of his right ear. She consulted various doctors and was seen in the children's department. The swelling was larger, and œdema of the right upper eyelid was apparent (fig. 12). Eversion of the lid under anæsthesia revealed a shallow ulcer (fig. 13), which histological examination showed to be tuberculous. The tuberculin skin reaction was positive, and later, when the preauricular adenitis became an abscess, tubercle bacilli were recovered. The child had been in regular contact with a phthisical aunt, who died a few months afterwards.

PRIMARY TUBERCULOSIS OF MOUTH

Up to now, excluding lesions in or on the tonsils, I have seen only 3 cases with proved tuberculous lesions in the mouth and regional tuberculous lymphadenitis:

(1) A girl, aged two years, developed a painless ulcer in her mouth and a submental adenitis after her mother had found her sucking several small sharp stones from the roadway. There was no known source of infection.

(2) A child, aged eight years, had a ragged painless ulcer over her upper incisors and a small, similarly painless, enlargement of her facial and submental lymphatic glands.

(3) A boy, previously healthy, came to hospital in April, 1949, with three weeks' history of a firm painless swelling of his right submandibular gland (fig. 14). Examination of his mouth revealed a circular ulcer on the gum of his right upper jaw (fig. 15). This ulcer was about $^{1}/_{2}$ in. in diameter, with raised and rather irregular edges and a red granulating base. The boy knew the ulcer was present but had not complained of it. He had had it for three weeks, and it had appeared fourteen days after two teeth had been extracted. Biopsy revealed tuberculous granulation tissue, and tubercle bacilli were later recovered from the gland. There was no known contact.

These 3 lesions were all conspicuous, and the regional glands were in no way distinguishable from many other cases in which no lesion was found in the mouth. The chances of infection in the mouth must be great, and it seems strange that we do not see tuberculous lesions in the mouth more often. Perhaps it is because we have not yet learnt to recognise them. In these 3 cases there was no history of contact; 2 had trauma to the mucosa; and all 3 had the combination of a painless mouth lesion with a regional tuberculous lymphadenitis.

CONCLUSION

This paper is concerned only with the recognition and simple description of the primary lesion of tuberculosis developing in visible sites on skin and mucosæ. In five years I have seen more than 30 cases, and here I have given details of 28. This form of infection must be more common than we have hitherto appreciated, and it must often go unrecognised. Yet it is important because collection and study of such cases should help our understanding of the pathogenesis and natural history of tuberculous lymphadenitis and might make a firm foundation for a study of the treatment of that condition. To the clinical scientist it is material for study which comes near to the conditions which are necessary for experimental work.

SUMMARY

28 cases of primary tuberculous infection are described: 20 of skin, 5 of eye, and 3 of mouth.

A history of trauma was present in 10 cases of skin infection and 2 in the mouth.

In 11 cases of skin infection there was a history of contact; in only 3 cases was there a history of both trauma and contact.

The appearances of the primary focus on the skin are determined largely by the presence or absence of trauma.

The lesion in the eye is usually under an œdematous upper lid.

The regional glands in all the cases have softened to form abscesses.

Although I have seen all these cases in the course of everyday clinical work, a consistent study has only been made possible by the help I have received from many friends in the pædiatric, surgical, ophthalmological, dental, and pathological departments of the Royal Victoria Infirmary, and from the Director and staff of the department of medical photography in King's College, Newcastle upon Tyne.

With illustrations on plate

Atelectasis, or failure in expansion of the lung, is often found in premature babies and commonly accompanies cerebral damage, aspiration of foreign matter, hyaline membrane, and congenital defects such as diaphragmatic hernia, œsophago-tracheal fistula, and pulmonary hypoplasia. In some of these conditions —and especially in prematurity—removal of the handicap of atelectasis would improve the chances of survival.

Every year in England and Wales about 14,000 children die in the first month of life, and of these about 2300 are certified as dying of asphyxia and atelectasis.

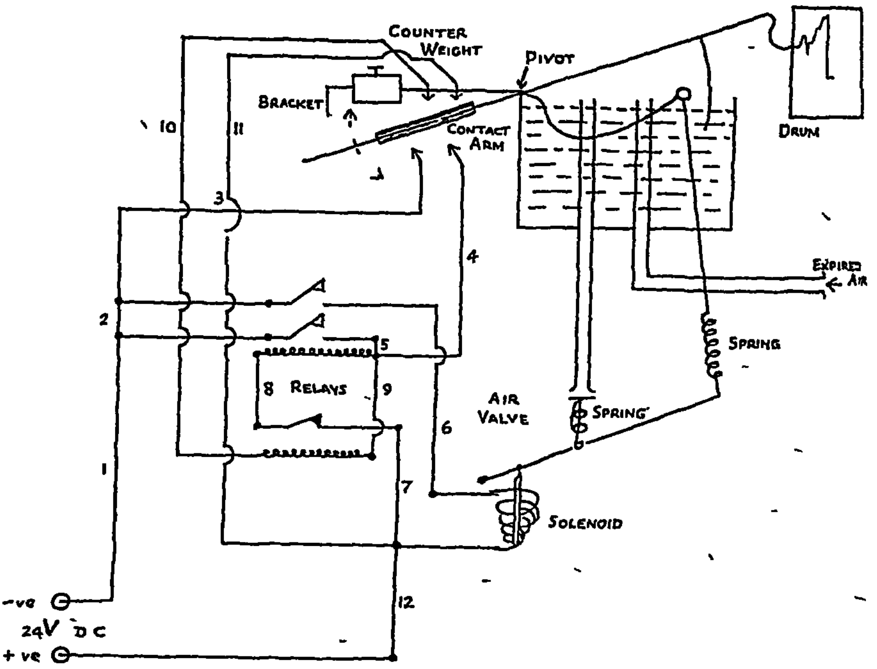

Fig 1—Trip spirometer

Cruickshank (1930) analysed the necropsy findings in 800 deaths in the first month and found that 540 of the deaths were due to asphyxia resulting from atelectasis, cerebral hæmorrhage, or prematurity Among the babies dying during the first day of life, premature birth was four times as common as full-term delivery Claireaux (1952), in a similar analysis of 100 cases in a consecutive series at Queen Charlotte's Hospital, found that 70 of the babies were premature, and 34 (48%) of these died from atelectasis and 18 (26%) from intracranial hæmorrhage

The standard treatment of atelectasis is largely a matter of laisser faire and relies on good nursing, airway clearance, and a supply of oxygen Particularly if premature, a baby with gross atelectasis may be too weak to avail itself of the oxygen, and fruitless inspiratory efforts exhaust it, so that within a few hours the struggle ends in peripheral circulatory failure

The servo respirator here described was evolved as a means of actively assisting lung expansion and rapid oxygenation, and, although the success of any such treatment may be reflected in the survival-rate of asphyxiated babies, its efficacy can only be assessed by an objective study of the rate and degree of pulmonary expansion so obtained A simple method of clinical spirometry has therefore been devised to assess respiratory efficiency of babies with atelectasis before and after treatment and to compare it with that of healthy infants

Trip Spirometer

The apparatus at present in use (fig 1) consists of a Krogh spirometer of known capacity in which expired air is collected via a simple non-return flap valve, so that the individual breaths are represented on a kymograph by a series of steps of different sizes arranged like a staircase The steepness of the staircase slope varies with the child's respiratory activity As soon as the spirometer float is filled, an electrical trip mechanism comes into play, and, by means of a simple system of relays, a solenoid lifts the balancing weight off the counter arm of the spirometer and simultaneously releases the accumulated expired air by opening a spring-loaded valve The float chamber immediately drops to the empty position, whereupon another relay circuit is closed This not only interrupts the solenoid circuit, thereby allowing the spring-loaded valve to close and the balancing weight to resume contact with the counter arm, but also interrupts itself, so that no current is used except in the process of emptying The spirometer then fills again with the next series of breaths, and the process is repeated A time-marker is used and a number (N) of complexes are thus traced over a known number of seconds (S), each complex representing the same known spirometer capacity (C) The minute volume is easily calculated by the following formula

$$\text{Minute volume} = \frac{N \times C}{S} \times 60$$

The size of each step gives an indication of the amount of tidal air (fig 2)

A more rough and-ready method is to measure the angle of slope of each complex with a protractor and then

The expired air is collected by using a rubber oxygen mask of U S Army pattern upside down so that the base fits over the forehead, including the eyes, and the chin fits into the apex, which would normally rest over the bridge of the nose in an adult This mask fits well and can be used on any size of baby

When the child is in the servo respirator, the trip spirometer is simply connected to the head or face chamber Until six months ago recording was by a variable-leak method (Paton 1949), but this was found to be inadequate in dealing with the intermittent and periodic breathing of premature infants, and calibrating errors were too great

Plethysmographic methods, such as that of Cro (1949), probably give more accurate results but involve disturbing an ill baby The above described method is sufficiently accurate for diagnostic purposes

Certain defects in the apparatus are admitted

(1) *Inaccuracies occur at both ends of the scale* very minute breaths are under registered owing to inertia, and very *large* breaths are exaggerated owing to overswing

(2) The concentration of carbon dioxide in the dead space of the mask tends to rise and may artificially stimulate respiration This is not a serious objection, because the periods of recording are necessarily short in the case of sick children and we are more concerned with maximum than minimum respiratory capacity

(3) *The figures for quiet respiration have to be tabulated* separately from those of crying respiration because the two are not comparable

(4) Any leak in the fit of the mask over the face causes under registration

The advantages of this method, however, easily outweigh the drawbacks in clinical practice

(1) The degree of atelectasis can be assessed without removing the child from its incubator or disturbing it any extent

(2) A record is obtainable within a few minutes, and the apparatus is very simple to use We have tested six babies in about three quarters of an hour, and this included proper cleaning of the mask between cases

(3) The apparatus can be constructed cheaply for only a few pounds if home made One of us (I D) built one in less than eighteen hours

We have taken recordings from healthy infants of all sizes and at different ages to find out what normal figures to expect. Our figures are higher than those of Cross and Oppé (1952), but this is because, in clinical work, it has not been practicable (even if desirable) to achieve absolute rest on the part of the baby for five minutes before recording. Babies with atelectasis or cerebral irritation are incapable of resting.

Expansion of the Lung

Lung expansion in the normal infant has been studied both by spirometry and by radiography.

Edith Potter (1952) believes that, normally, all alveolar ducts and alveoli are expanded within the first few minutes of extra-uterine existence, and Morrison (1952) states that lung aeration is more or less complete shortly after birth, although areas of non-aeration may persist for many days, particularly in premature babies.

Clement Smith (1951), on the other hand, claims that some degree of primary atelectasis may persist for more than a week after birth in quite normal babies.

Most radiographs of the chest during the neonatal period are taken during expiration. The newborn infant has a small volume of residual air; so differing opinions have been published about the rate of expansion of normal lungs. Our own radiographs taken within thirty minutes of birth in normal cases show full aeration (fig. 3), but spirometry gives readings which are directly proportional to the birth weight and increase considerably during the first twenty-four hours of life. This increase in the case of the healthy infant usually levels off within forty-eight hours.

Lung Expansion in Abnormal Infants.—The above-mentioned standards have to be modified in the light of prematurity, anoxic depression, atelectasis, and cerebral irritation, or the subsequent development of pulmonary disease; in fact, readings may run parallel with the progress of the case and may fall progressively.

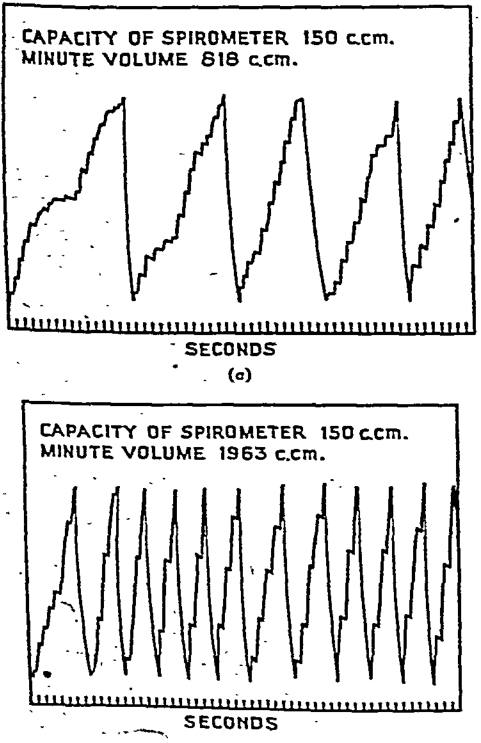

Fig. 2—Specimen tracings from normal baby (birth weight 6 lb. 12 oz.) at ages of (a) 12 minutes and (b) 25 hours.

Pathology and Rationale of Treatment of Neonatal Asphyxia

The small premature baby has a relatively inadequate surface area in the lung available for respiratory exchange, and the blood-supply to the air sacs is small. The infant has weak respiratory muscles with which to overcome the cohesion of the moist walls of the air-passages. If those parts of the lung which are sufficiently mature are not expanded promptly, the baby is liable to suffer irreversible damage from asphyxia.

Asphyxia, in mature as well as premature babies, is most commonly due to intra-uterine anoxia. Firstly, the stimulus of anoxia may cause premature respiratory efforts, with the inhalation of liquor amnii and debris. This is absorbed or eliminated by the healthy infant, but it may be lethal to the baby already damaged by intra-uterine anoxia.

The most important effect of this anoxia is congestion of the fœtal veins and capillaries, accompanied by hæmorrhages and œdema. In the brain the resulting circulatory embarrassment makes the respiratory centre unresponsive. In the lung the congestion and hæmorrhagic œdema of the parenchymal tissue impair expansion. In fact full expansion may be long delayed or may never take place. The pulmonary air sacs, too, contain excess fluid, which so limits aeration that their capillaries continue to be filled with venous blood. This alters the permeability of the capillary walls and causes increasing pulmonary œdema of local origin. This fluid cannot be absorbed by a failing circulation. In addition, some asphyxiated babies have generalised œdema at birth. If there is a widespread but compensated excess of extravascular fluid, the absorption of fluids from the lungs will be delayed. Also, elimination of these fluids via the air-passages is slow when the baby suffers from shock and poor muscle tone. In such a baby partial absorption or elimination of fluid may be followed by further atelectasis (resorption non-aeration).

An initial atelectasis may thus cause death within the first few hours, or the baby may remain in a damaged and precarious state for several days.

Atelectasis is both the effect and the cause of anoxic damage to the fœtus. Expansion of the lung will promote oxygenation, aid the elimination of pulmonary fluid, and improve the circulation. Most of the severely asphyxiated full-term babies soon achieve an adequate lung expansion after pharyngeal aspiration and the prompt administration of endotracheal oxygen. Some small premature infants, nursed in a warm oxygen tent and given postural drainage and gastric oxygen, likewise do well. In others regular respiratory efforts are achieved, but the signs of atelectasis persist. These babies are considered to be in urgent need of oxygenation, and an attempt is being made to break the vicious circle of anoxia, œdema, and atelectasis by gentle and gradually assisted lung expansion with the servo respirator.

SECONDARY ATELECTASIS

Though primary atelectasis is common, true secondary atelectasis, in which collapse of the lung follows adequate expansion, seems to be rare. It may be secondary to traumatic cerebral damage or to certain congenital defects, but usually these conditions are associated with an initial non-aeration. In certain conditions inspired debris or infected material, which at first moves freely in the air-passages, may become plastered round the bronchioles and proximal air sacs, causing pulmonary collapse, possibly with the formation of a hyaline membrane, or even causing pneumonia.

The necropsy finding of "atelectasis" in a child who showed previous evidence of adequate pulmonary expansion is of doubtful significance. Potter (1952) claims that secondary atelectasis is found at necropsy in almost all infants who die in the first few weeks of life; but in the

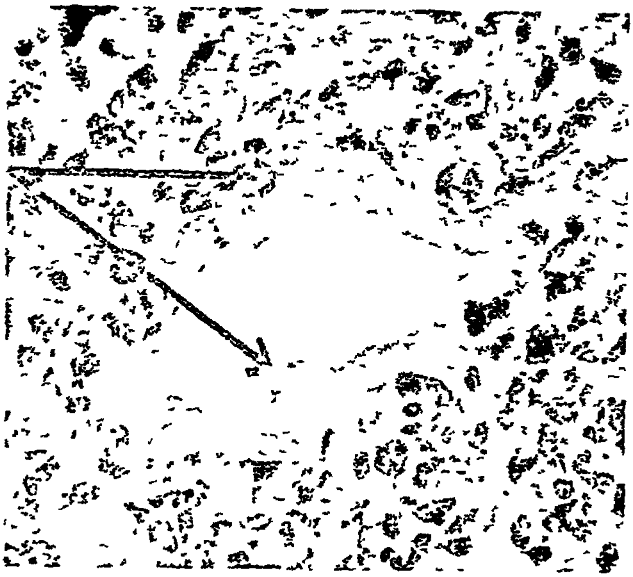

Fig 7—Twin D1 Hyaline membrane in alveolar duct

absence of hyaline membrane it is not the primary cause of death The newborn lung is highly elastic and contains little residual air A large share of this is absorbed during the agonal period

We are studying, by radiography and spirometry, the evolution of "secondary" atelectasis It is possible that, if the child can be kept oxygenated by aided respiration, the condition may be self-limited or reversible

It is interesting to note the development of atelectasis in five of our cases which came to necropsy Initial respiratory difficulty had originally been present at birth in all of them

Triplet L3 achieved a minute volume of 1100 ml after treatment with the servo respirator but died some hours later The lungs were solid, and hyaline membrane was present

Baby Su breathed promptly if inadequately at birth but died after 8 hours, with total non aeration of the lungs and again hyaline membrane

Baby Je showed at necropsy no evidence of ever having breathed though it was grunting on admission, lived for 5 hours, and was observed breathing, and though radiography at the age of 4 hours showed some aeration of the right base (fig 4) This is a point of some forensic importance Air (4 ml) was present in the stomach and probably supplied the greater part of what little oxygen the baby received

Baby D1 had minute volumes (after respirator treatment) of 1150 ml and 1050 ml 2 hours and 1$^1/_2$ hours respectively before death, *yet at necropsy only the anterior aspect* of the right upper lobe was aerated (figs 5 and 6) All the remainder of the lung tissue was solid Hyaline membrane was present (fig 7)

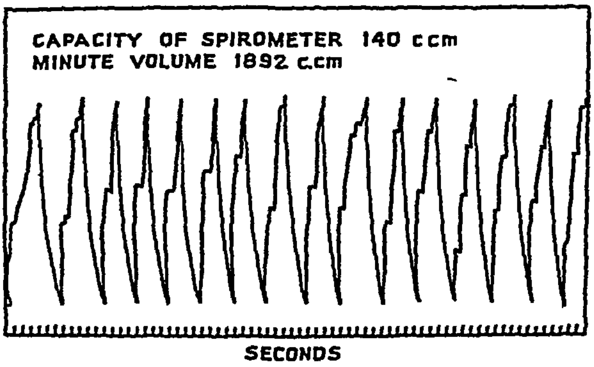

Fig 8—Baby Aa aged 22 hours Spirometer tracing

Baby R1 showed, radiologically, full expansion at 9 h and just before and immediately after the moment of de yet at necropsy the picture was that of partial atelec chiefly affecting the lower lobe of each lung, many of t *alveoli and alveolar ducts being filled with cornified* c and acidophil fluid owing to excessive aspiration of liq amnii There was no hyaline membrane Death was d to subdural and subarachnoid hæmorrhage as the result asphyxia The child weighed 2 lb 12 oz, and was admit at the age of 1 hour Clinically there was no evidence air entry, rib recession was pronounced Minute volume *348 ml and 360 ml were recorded at 5 hours and 12 hour* which were considered reasonably adequate in relation birth weight, and because of this, as well as the satisfacto radiographs, the respirator was not switched on Death which took place at 29 hours, was *correctly* attributed to intracranial hæmorrhage

Spirometry as a Diagnostic Aid

Spirometry helps to clarify the clinical diagno at least in the direction of excluding atelectasis

Baby Aa weighing 7 lb 13 oz, was delivered after a rapid second stage with fœtal distress Its condition for the next 2 days was unsatisfactory, and atelectasis was diagnosed Spirometry at 22 hours, however *(crying), recorded 1802 ml* minute volume (fig 8), and the diagnosis was disputed, treatment with the servo respirator was therefore withheld Next day chest radiography showed pneumonic consolidation of the right middle lobe with lung fields otherwise clear (fig 9) The child recovered

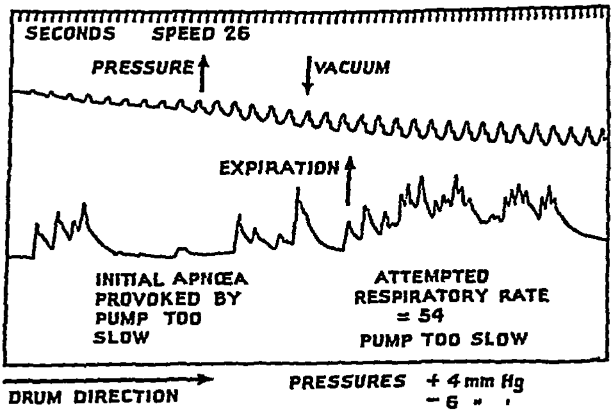

Fig 11—Baby, aged 23 minutes birth weight 1 lb 15 oz Spirometer reading with artificial respiration not adjusted to natural respiratory rhythm (variable leak method)

The spirometer is even more useful in assessing the degree and progress of established atelectasis We have had two sets of twins and one set of triplets in which, by spirometry, we were able to select the most severely affected with atelectasis for treatment in the respirator

Triplets L were delivered in the 33rd week The first born, L1, weighed 3 lb $^1/_2$ oz, and at 1$^1/_2$ hours the minute volume was 450 ml, which was regarded as satisfactory, and the respirator was not used L1 progressed well on its own and, during a phase of crying, *at 8 hours achieved a recording of* 1021 ml, a figure which was not again reached during the *next 4 days* This suggests that the baby achieved full expansion in the first 8 hours The other two triplets are described in more detail below

Baby RcR was interesting It was delivered naturally at 32 weeks gestation and weighed 3 lb 7 oz Its condition initially was good At 45 minutes, when it was breathing quietly, its minute volume was 235 ml, and it was decided to *observe progress before putting it in the respirator* At 11 hours the minute volume had increased to 304 ml, and at 35 hours it was 701 ml On the 3rd day, however, the baby s condition deteriorated, and the minute volume was found at 56 hours to have fallen to 397 ml Apnœic attacks developed and cerebral irritation was diagnosed *Radiography* a few hours earlier revealed a spontaneous pneumothorax on the *right side (fig 10) The respirator had not been used*

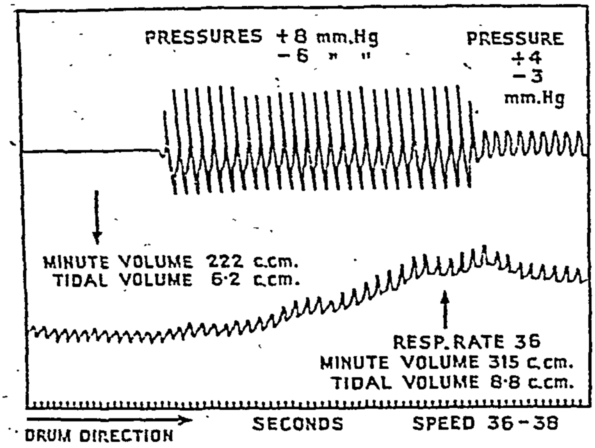

Fig. 12—Baby, aged 2 hours, born at 29½ weeks. Spirometer reading with artificial respiration adjusted to natural respiratory rhythm (variable leak method).

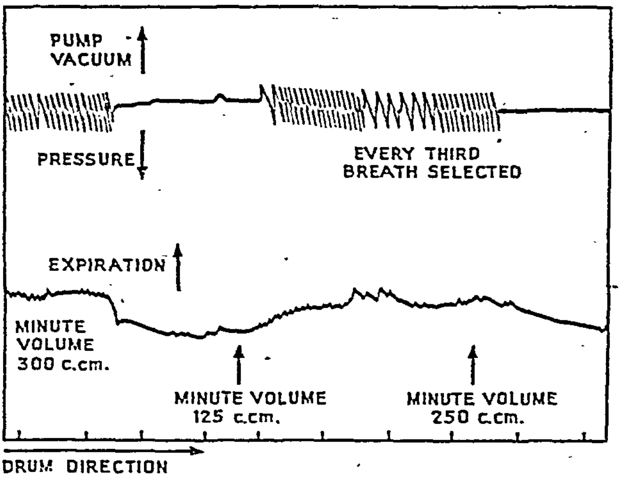

Fig. 13—Baby, aged 9 hours; birth weight 1 lb. 10¼ oz. Spirometer reading with amplified respiration (variable leak method).

Servo Patient-cycled Respirator

This apparatus has no place in the treatment of asphyxia at birth due to fœtal shock. It has been designed to deal with cases in which the signs of atelectasis persist or develop subsequently. The large majority of infants in this category are premature.

Considerable experience was gained originally with a Drinker type of apparatus in which speeds of operation and pressure could be varied within wide limits by means of a crank of variable throw driving a large-capacity bellows. Results obtained, however, were never convincing, even when the child survived. One of three things usually happened:

(1) The baby fought the rhythm of the machine with its own variable rhythm if strong enough to do so, with the result that, at best, no good was done.

(2) The baby promptly went into apnœa—we call this "protest apnœa"—after which some large breaths might or might not be forced on it.

(3) Alkalotic tetany was liable to develop as a result of hyperventilation; it was therefore considered unsafe to leave the apparatus switched on for more than three consecutive minutes at a time.

It was not until the taking of recordings was instituted that the limitations of the Drinker principle became apparent in treating the newborn. At that time, the trip spirometry method had not been developed, and the variable-leak method was in use. This served at least to reveal what was wrong.

Figs. 11 and 12 show the striking difference in efficiency achieved when it was possible to adjust the respirator so that it was exactly in step with the baby's natural rhythm.

It became obvious that what was needed was a machine which would amplify spontaneous respiratory efforts however irregular. This has been achieved with a photo-electric pick-up mechanism whereby, by means of a light mirror attached to the flap of the inspiratory valve, the very start of each inspiration (the first 0·1 or 0·2 ml.) causes a light beam to be deflected from a photo-electric cell. The resulting electrical impulse is then amplified to trigger the machine into action. The baby therefore controls the machine with its own feeble respiratory efforts, the danger of alkalosis is removed, and the machine can safely be run for hours on end. This principle of respiratory amplification seems to be physiologically sound.

Cranks, bellows, and pistons have too much inertia to be of any use in such a machine. The operating pressures are therefore tapped from vacuum and pressure reservoirs by solenoid-operated valves. The apparatus and its circuit have been described elsewhere (Donald and Young 1952). The effect on respiration is shown in fig. 13, while fig. 14 illustrates one form of the present apparatus.

SEALING THE FACE

For the proper operation of the sensitive photoelectric pick-up, and also for accurate recordings, it is essential to have an efficient method of sealing the neck or face from the main body chamber.

Inflatable cuffs and sponge-rubber seals were discarded because, even with considerable contact pressure, which is undesirable, they remain inefficient and permit "pistoning" of the whole child. A search for a suitable plastic material which could be poured or squirted into place and would then set, without pressure, to the consistence of firm wet rubber led to the present use of an alginate ('Duplit') which contains sodium triple phosphate as a retarder and sets in about three minutes. This material is non-toxic and harmless. We mix it with water in roughly equal volumes in ordinary kitchen

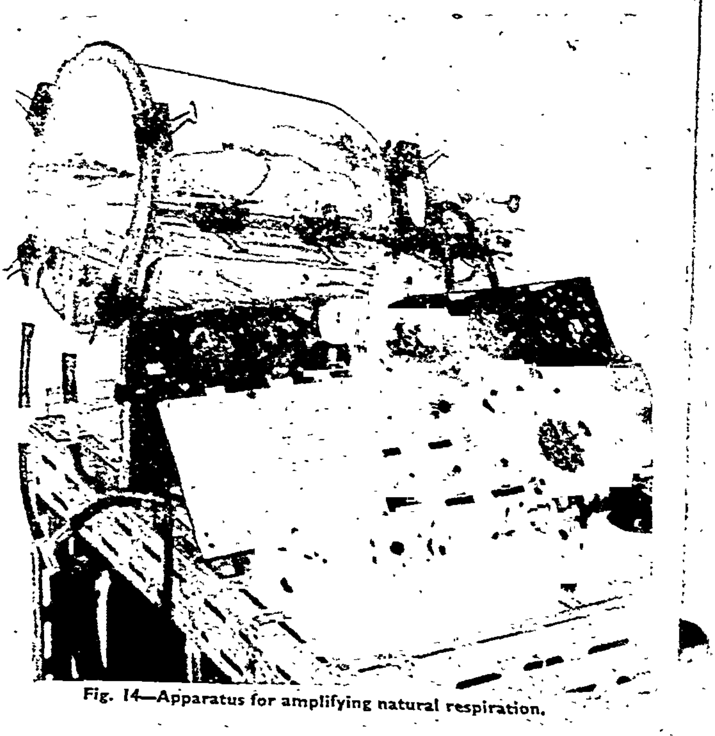

Fig. 14—Apparatus for amplifying natural respiration.

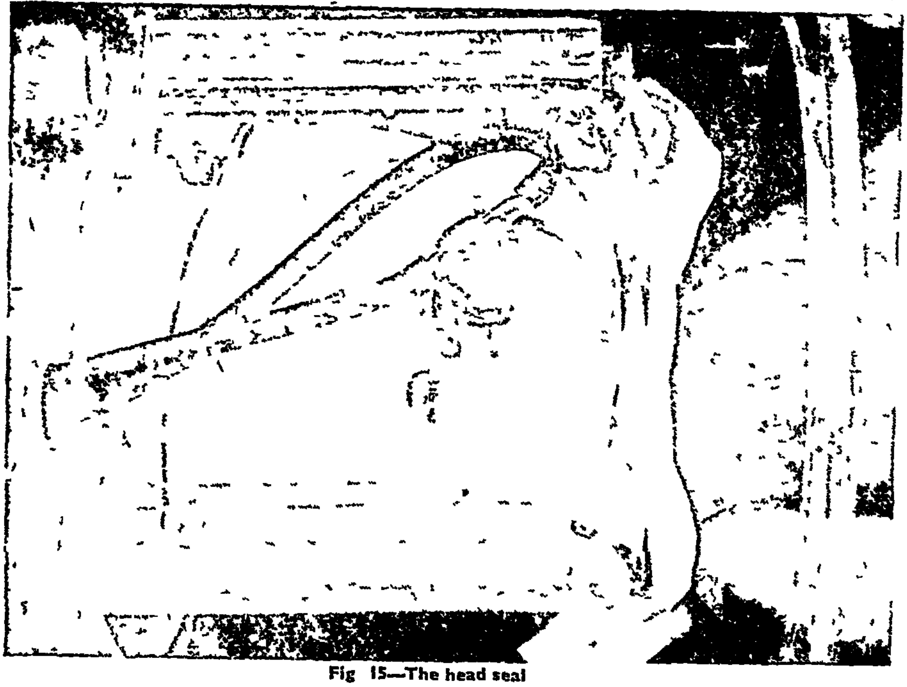

Fig 15—The head seal

egg-mixers The addition of glycerin seems to increase the durability of the seal but prolongs the setting-time, and experiments to improve the mixture continue

This material flows readily into position and conforms with all the natural shapes and crevices of the child's neck

Two alternative methods of sealing are used according to the requirements of the case Firstly, the neck may be sealed by injecting the solution by means of a metal ear syringe between two light latex diaphragms round the child's neck Although a firm fat cushion is thus formed between shoulders and occiput, slight pistoning due to elasticity is still liable to take place Though it does not interfere with treatment, this prevents accurate recording, and light metal baffle plates are necessary Even then a displacement compensator, connected with the outside atmosphere, has to be adjusted to eliminate recording errors completely

The second and newer method is therefore preferred A latex bib, edged with a wire half loop, is applied round the neck, and the child is laid in a sliding 'Perspex' trough with a deep well for the head The alginate is then poured into the well until the entire head and neck, except the eyes, nose, and mouth, are submerged Into this setting helmet the face mask is embedded, and the perspex trough is slid into the respirator case on runners (fig 15) After setting, the whole case can be rotated half-way to one or other side if desired Normally 50% oxygen and 50% nitrogen mixtures are carburetted and supplied at atmospheric pressure, but the proportions can be altered at will

The alginate breaks away very easily in the fingers and removal of the seal is therefore easy

After birth the routine resuscitative measures are applied as usual or appropriate, particularly the extraction of mucus Only when atelectasis persists is the respirator considered, and this may not be for an hour or two after birth In such cases oxygen supplied through a fine 'Polythene' tube passed into the stomach (Ylppo 1935) as a temporary measure often gives a period of grace for the transfer of the baby to the respirator a manœuvre which must not be hurried

CONTROL OF PRESSURE CYCLES

The operating pressures are determined by aircraft

seconds Allowances have to b made for changes in baromet pressure, but the corrections be applied are read directly fro an altimeter

The pressure waves can al be altered in form by bla gates on the reservoir manifol system

Either negative pressur (only) can be used, or th full cycle can be operated a desired With an electron "weld-timer" filter it is possible to select only a proportion of the child's breaths for ampli fication, and this is useful where respiration is very rapid

OPERATING PRESSURES

Minimum effective pressures are sought because the range of safety is not yet fully known The negative pressures applied to the body are potentially dangerous, but we have found pressures up to −40 cm of water harmless. The alginate seal, however, will not remain competent at these levels, and the usual ranges of *−15 to −30 cm* of water suffice

FOR
GRAVITATIONAL
SYNDROME

Some Results with Servo Respirator

A careful watch at necropsy has been kept for signs of pulmonary damage, but none has been found in any case save the following:

Baby N, weighing 4 lb. 12 oz., with hydrocephalus and spinal deformity, was stillborn after spinal tapping for the aftercoming head. An endotracheal tube was passed, and the body was at once transferred to the respirator, which was set in action for 2 hours with increasing negative pressures. No respiratory movements were observed at pressures of −40 cm. of water, some were evident at −55 cm. of water, and movements were very pronounced at −80 cm. of water.

At necropsy the lungs were hypoplastic, each weighing only 5 g. All sections floated (although the child was stillborn). Bilateral pneumothorax and mediastinal emphysema were present, and the lungs were extensively damaged by bullous emphysema. There was no visible rupture. Microscopy showed areas of overdistension alternating with atelectasis. Moderate hypoplasia was evident.

These observations on dead and hypoplastic lung encourage one to believe that the safety margin is wide.

Baby D1, weighing 6 lb. 5 oz. (already referred to in the section on secondary atelectasis), was delivered by cæsarean section for antepartum hæmorrhage with fœtal distress. There was difficulty with respiration at first. Signs of atelectasis were very pronounced at 7 hours, and the condition deteriorated, necessitating intubation at $9^1/_2$ hours, and positive oxygen pressures were intermittently applied. At 11 hours its state was critical, and it was transferred to the respirator with the endotracheal tube still in situ to guarantee an airway. Considerable progress was achieved, but the child became cyanosed whenever the machine was switched off, and improvement was never long maintained. Mucus was from time to time copiously produced and had to be sucked out. Negative pressures of up to 65 cm. of water were applied, being possible in the absence of an alginate seal and with the use, instead, of the endotracheal tube. After $6^1/_2$ hours' intermittent treatment some of the apparatus was accidentally smashed. The child's condition being at that time fairly satisfactory it was transferred to an oxygen tent. It died suddenly 20 minutes later. Death was due to extensive hyaline membrane. In spite of the recklessly high pressures used there was no evidence of pulmonary trauma.

Baby Rh was one of twins born at 29 weeks' gestation. In spite of gastric oxygen and routine resuscitative measures, signs of atelectasis persisted. Spirometry confirmed that the baby's condition was much worse than that of its twin sister (birth weight 2 lb. $^1/_4$ oz.). The baby was placed in the respirator, and respiration was amplified, pressures of −30 cm. and +15 cm. of water being used. Later the positive pressures were discarded. After $3^1/_2$ hours' treatment the physical signs of atelectasis had disappeared. Radiography at 8 hours showed normal expansion. On the 6th day the baby weighed 1 lb. 14 oz., and it was discharged fit after 10 weeks, weighing 5 lb. $7^1/_2$ oz. The untreated twin also survived.

Baby Ku was delivered by cæsarean section, because of severe pre-eclamptic toxæmia, at 32 weeks' gestation. It weighed 3 lb. 4 oz., and its condition at birth was very bad. There was no spontaneous respiration. An endotracheal tube was passed, and positive oxygen pressure was applied, but at once collapse became serious. The baby was transferred thereupon to the respirator and, as there were no spontaneous respiratory efforts to amplify, the emergency control was switched on. This was without effect, and the heart stopped in 20 minutes. On removal the tube was found to be blocked. Necropsy revealed gross atelectasis and generalised signs of asphyxia.

This experience illustrates the dangers of intubating premature infants. We now regard gastric oxygen as safer and more effective.

Baby RcM was delivered by cæsarean section, because of severe pre-eclamptic toxæmia, at 31 weeks' gestation. It weighed 3 lb. 3 oz. and gasped at once. Signs of atelectasis were not gross and had fully disappeared after 4 hours in the respirator. The baby was discharged fit on the 69th day, weighing 6 lb. $4^1/_2$ oz. Unfortunately, as the spirometer was not available for this case, proof of benefit is lacking.

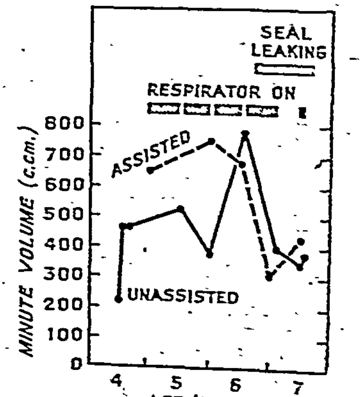

Fig. 16—Baby B. Spirometer readings in respirator.

Baby Su was delivered by abdominal hysterotomy at 26 weeks' gestation because of pre-eclamptic toxæmia and malignant hypertension, which caused the mother's death a few weeks later. It weighed 1 lb. 7 oz. and breathed promptly at birth. After transfer to the respirator it appeared to achieve moderate chest expansion, but a technical fault developed in the photo-electric cell amplifier, after which the

MR. MOORE

Fig. 1 (case 3)—Thin indurated leg with large ulcer and severe equinus deformity. Venogram shows thin veins which have thrombosed and recanalised. Patient was cured by popliteal ligation after other methods had failed.

Fig. 2—" Moth-eaten " appearance of veins which have thrombosed and recanalised.

The patient, a woman aged 48, had had ulcers of the legs for 12 years. History of " white leg " 21 years ago and 12 years ago, but no varicose veins.

Fig. 3—Smooth outline of veins in which no valves can be seen.

The patient, a woman aged 30, was admitted as an emergency with extensive bleeding from a varicose ulcer. Ulcers had been present for 2 years and were getting worse. Varicose veins from the age of 13, becoming worse at 25 after postpartum " white leg." This appearance of the veins can occur either without apparent cause or following thrombosis of the pelvic veins (Moore 1951).

Fig. 4 (case 1)—Venograms of right (*a*) and left (*b*) legs in September, 1950, and of right leg (c) in April, 1951.

(*a*) Right leg in 1950 is normal, showing posterior tibial, peroneal, and anterior tibial veins with numerous valves. Popliteal vein is double, and " fish-tail " appearance of a normal valve can be seen in lateral view. Femoral vein is well outlined and shows, faintly, three valves. Muscular veins are in two groups, best seen in lateral view. There are no connections with superficial veins.

(*b*) Left (affected) leg in 1950 shows partial thrombosis of femoral vein, seen over lower part of femur (entire femoral vein was similar). Popliteal vein is narrow but intact: this was confirmed at operation, at which another large thrombosed vein was found which may have been a second popliteal, as in right leg. Veins of leg are small and muscular veins more prominent than usual but not otherwise affected.

(c) Right leg in April, 1951, about three months after onset of symptoms in this leg. Change from 1950 (*a*) is striking. Partial thrombosis of femoral and popliteal veins is well seen. Veins of the leg, although narrow, as though in spasm, are not obviously abnormal. Long saphenous vein is well filled.

Fig. 5—Old deep venous thrombosis, with complete block at upper end of popliteal vein and collateral channels proceeding up from site of obstruction.

The patient, a woman of 53, had had ulcers of the leg for many years, and varicose veins which had followed postpartum " white leg " 20 years previously. The leg did not improve after ligation of popliteal vein.

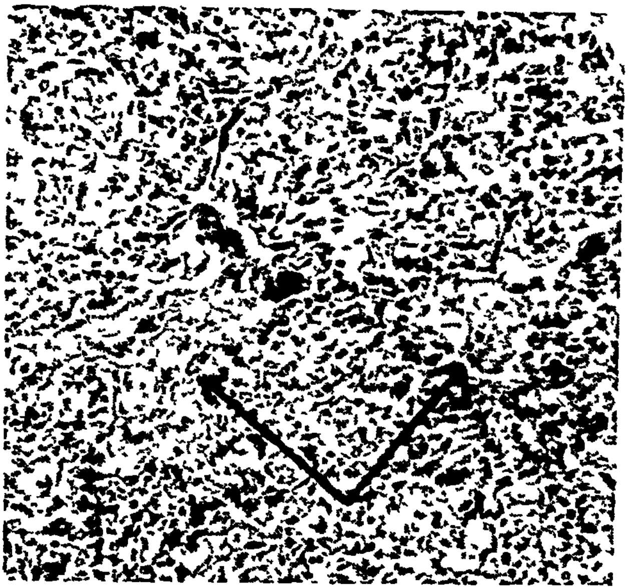

Fig 18—Baby B, post mortem Mucus plugs in bronchioles, without hyaline membrane

signs of rib recession increased The baby was kept alive with the help of the emergency switchgear for a further 2 hours but died at the age of 8 hours At necropsy the lungs were solid, and extensive hyaline membrane was found on microscopy

Baby F1 was aborted at 26 weeks' gestation and weighed 1 lb 11 oz It was immediately placed in the respirator Spirometry was impossible because the respirations were too minute, nevertheless the photo electric mechanism worked well, and respiration was amplified for 8 hours, by which time the baby appeared well enough for transfer to an incubator

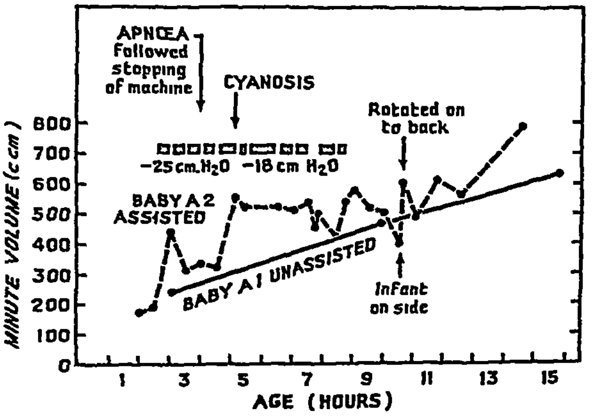

Fig 19—Twin A Spirometer tracing showing improvement in baby A2 while in respirator

Chest radiography at 12 hours showed no evidence of consolidation or deflation Nevertheless death took place at the age of 26 hours At necropsy both cerebral ventricles were full of blood from a ruptured subependymal vessel on the corpus callosum The lungs were moderately well expanded The two lower lobes sank in water, but the remaining lobes floated

Baby B, aged 1½ hours, was admitted from outside in bad condition, having been born at 34 weeks' gestation and weighing 3 lb 11 oz *Mouth to mouth insufflation* had been used Atelectasis was clinically gross, and the minute volume at 4 hours was only 220 ml Fig 16 shows the dramatic improvement obtained in the respirator, but the head seal became incompetent after 2 hours (this is shown by the intersection of the two lines on the chart), and since the child seemed better it was transferred to an incubator instead of setting another seal *This was clearly a mistake* Its condition was satisfactory at 15 hours, but it died at 27 hours after recurrent attacks of cyanosis

Radiography at 4 hours, 8 hours (fig 17), and post mortem showed left basal atelectasis and fine mottling throughout the lung suggesting alveolar atelectasis in increasing degree At necropsy aeration appeared good macroscopically, but histology showed numerous mucus plugs in the bronchioles but no hyaline membrane (fig 18) There was a small intracranial hæmorrhage Good pulmonary ventilation was achieved with the apparatus but diminished after the apparatus was switched off, and the lung pathology persisted

The question arises whether the mucus plugs represented an early stage in *the formation of hyaline* membrane

Twins A1 and A2 were admitted from a nursing home about an hour after premature delivery at 31 weeks' gestation Baby A1 weighed 3 lb 1½ oz, was in fairly good condition, and had a minute volume of 230 ml Baby A2 weighed 3 lb 9½ oz, had a minute volume of only 170 ml, and had a bad colour She stopped breathing shortly after arrival and appeared to be so moribund that it seemed unlikely that transfer to the respirator would be achieved in time Gastric oxygen, however, *revived her, and the tracings in fig* 19 show the improvement achieved with the apparatus A further period of observation having satisfied us that progress was being maintained, the head seal was removed and the child was placed in an incubator Chest radiography at 6 hours *while the baby was still in the respirator* and after 4 hours' treatment, showed satisfactory pulmonary expansion Baby A1 maintained fairly steady spontaneous progress, and the twins are now thriving at the age of 5 weeks

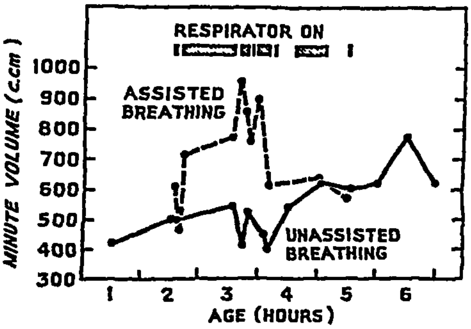

Fig 20—Triplet L2 Spirometer reading showing improvement while in respirator

Triplet L2, born at 33 weeks' gestation of a pre eclamptic mother, was clinically the worst of the three, had a minute volume of 420 ml, and weighed 4 lb 1½ oz Triplet L3 appeared only *a little less fit*, was smaller, *weighing* 3 lb *15 oz*, and had a minute volume of 390 ml Triplet L1, as already mentioned, was reasonably well Triplet L2 was therefore placed in the respirator, and fig 20 traces its progress After 2½ hours' treatment the minute volume appeared fairly stable at about 620 ml, the baby's colour was very good, and only slight rib recession persisted Chest radiography at 6 hours—i e, after treatment—*showed full lung expansion* (fig 21) It is interesting to compare this with the radiograph at the same age of triplet L3, which had not then been treated (fig 22)

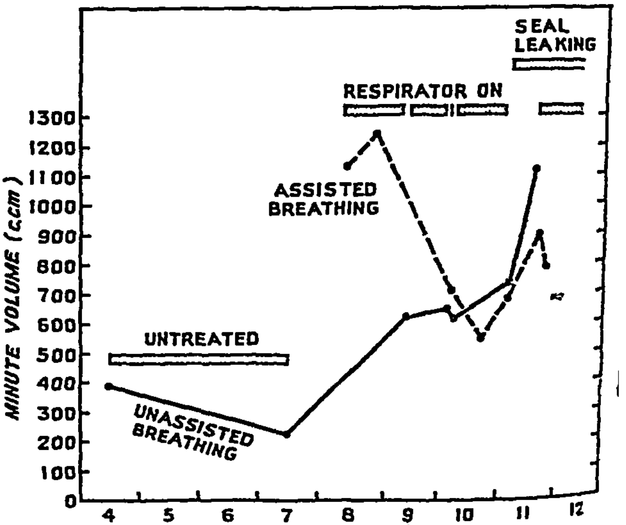

Fig 23—Triplet L3 Spirometer readings in respirator

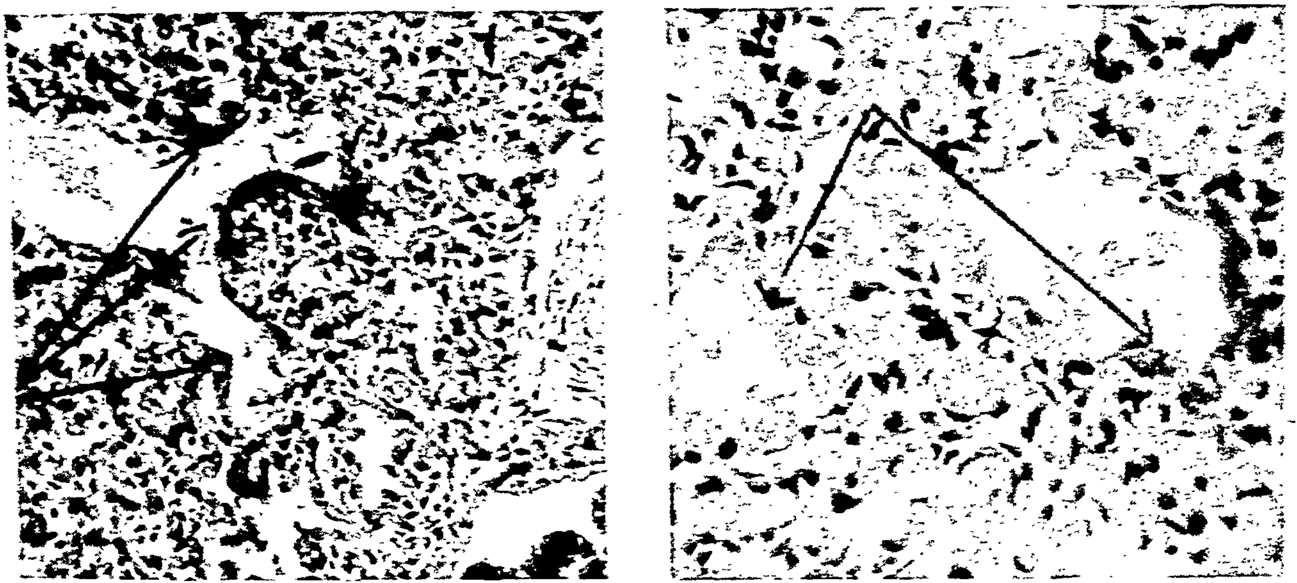

(a) (b)

Fig. 24—Triplet L3; after death aged 20 hours. Hyaline membrane in (a) distended alveolar duct and (b) alveoli.

At 5½ hours triplet L2 had to be removed from the respirator to make way for triplet L3, who was by now very cyanosed in its incubator and whose condition, due to gross atelectasis, appeared to be critical. Triplet L2 after removal made uninterrupted progress and at the age of 4 days had the best minute volume (553 ml.) of the three. It was discharged home weighing 6 lb. at the age of 4½ weeks.

Triplet L3, as already mentioned, deteriorated under routine treatment and at 7 hours the minute volume had dropped from 340 to 230 ml. The baby was placed in the respirator, and at once its colour and general condition improved. Unfortunately after 2½ hours the seal became incompetent. Fig. 23 shows the good progress at first, and then crossing of the assisted and unassisted recording tracings. This occurs with seal leakage owing to the diversion of some of the expired air into the main body chamber as a result of the negative pressures there. The apparatus, to say nothing of the attendants, was showing signs of fatigue and of overheating of some of the working parts. At 12 hours a new seal was applied, but treatment was not persisted with, because the baby was crying vigorously, and at 18 hours it was transferred to the oxygen incubator. Thereafter its condition deteriorated, and even gastric oxygen did not improve its colour. It was thought to have intracranial hæmorrhage and was not disturbed. Death took place at 20 hours, and necropsy revealed solid and œdematous lungs, microscopy showing hyaline membrane (fig. 24). There was no cerebral hæmorrhage.

Summary

An account is given of neonatal atelectasis, and its pathology and diagnosis are discussed.

A simple method of clinical spirometry is described together with its practical applications in differential diagnosis and assessment of pulmonary efficiency.

An interim account is given of a patient-cycled servo respirator designed to treat atelectasis and of our experiences with it. Three cases and possibly a fourth might be claimed as successful results so far as life-saving is concerned, but the disappointment-rate is very high—often because of imperfectly developed technique and sometimes because of complicating conditions such as intracranial hæmorrhage. As an obstacle, hyaline membrane has loomed large, being confirmed at three necropsies. We do not yet know whether this condition is irreversible, but we wonder whether triplet L2 would have succumbed to it in place of triplet L3, which was treated belatedly, had their positions been reversed.

We are indebted to Dr. A. Claireaux for the detailed necropsies and to Dr. R. E. Steiner for the radiological reports. A project of this magnitude could not have been launched without help from sources too numerous to acknowledge, from colleagues both at Hammersmith Hospital and St. Thomas's Hospital, and from friends in the Royal Air Force and Fleet Air Arm who have given much technical advice. We would like also to express our appreciation of the encouragement received from Mr. A. J. Wrigley, Dr. J. Forest Smith, and Professor Moncrieff, and of financial assistance from the endowment fund of St. Thomas's Hospital, where much of the present apparatus was originally developed.

THE ANKLE BLOW-OUT SYNDROME

A NEW APPROACH TO THE VARICOSE ULCER PROBLEM

F. B. COCKETT

With illustrations on plate

In a paper by H. E. Lockhart-Mummery and J. Hillyer Smitham (1951) the clinical problem of varicose ulcer is clearly stated. They found that their numerous cases fell into three main groups:

1. Those with varicose veins, often large and tortuous, whose skin in the lower third of the leg was perfectly healthy.
2. Those with pigmentation, induration, and ulceration of the lower third of the leg, but with no varicose veins.
3. Those with varicose veins in the thigh and leg, and ulceration.

In this last group, the ulcers were not always cured by dealing with the saphenous incompetence, and often returned when apparently cured in the first instance.

These facts have been repeatedly emphasised by all who have reviewed large numbers of such cases

(Cokkinis 1933, Homans 1939, Wright 1931, Bauer 1942) Hanschell (1949) sums up the problem admirably

> "The great majority of patients with varicose veins, at all ages, have and have had no leg ulcers, while the great majority of patients with leg ulcer, at all ages, have and have had no varicose veins, that in its clinical features, under all conditions, there is no discernible difference between ulcer with, and ulcer without, varicose veins"

Thus it almost seems that there are two separate diseases afflicting the leg—varicose veins and varicose ulcer—and that the two conditions may be quite distinct and separate and may apparently bear little relation to each other

The truth of the foregoing observations has been amply confirmed by our experience in the varicose vein and varicose ulcer clinics at St Thomas's Hospital over the past two years Recently one of us has attempted to analyse and sort out the varieties of ulcer of the leg which present themselves under the ubiquitous title of varicose ulcer (Cockett 1951) After excluding the purely traumatic ulcers, the infective ulcers, the arteriosclerotic ulcers, and the ulcers in erythrocyanoid legs we were left with the group which might for want of a better term be called varicose ulcers Four facts about these ulcers struck us forcibly

(1) These ulcers are situated most commonly in the lower third of the leg, usually on the inner side just behind and above the internal malleolus, and more rarely a similar site on the outer side of the leg They seldom transgress on to the foot or the upper third of the leg One commonly accepted explanation of these facts has been that the ulcer on the inside of the ankle is at the bottom of the column of blood in an incompetent great saphenous vein, and that the ulcer on the outside of the ankle is at the bottom of an incompetent small saphenous vein The treatment of these ulcers by high saphenous ligation and stripping of the veins is based on these supposed facts

(2) Many long-standing cases of gross incompetence of the great and short saphenous veins do not develop ulcers Conversely, many people are seen with ulcers in whom no incompetence of the superficial veins can be demonstrated

(3) Adequately performed ligation or stripping of incompetent superficial veins failed to cure varicose ulcers permanently in a high proportion of our cases

(4) A high proportion of varicose ulcers can be induced to heal with the patient ambulant by the simple expedient of continuous pressure over the ulcer—maintained by a 'Sorbo' or felt pad under a firm elastic-webbing bandage This point was first emphasised by Dickson Wright (1931)

To Homans (1916) and Bauer (1942) we owe the next step in our knowledge of the ætiology of these ulcers They established beyond doubt that some of these ulcers, particularly those not associated with varicose veins, were the result of previous deep-vein thrombosis Moreover the number of patients who got ulcers after deep thrombosis increased with the time elapsing after the deep thrombosis This is shown by the following table based on a long follow-up of 100 cases of deep thrombosis (Bauer 1942)

No of years after thrombosis	*Percentage of cases with indurative lesions of lower leg*	*Percentage of cases with ulceration*
5	45	20
10	72	52
Later	91	79

Studying the material from our own varicose ulcer clinic we found that 27 out of 80 cases of varicose ulcer were obviously related to previous deep vein thrombosis Now, although this is a most important finding it does not explain exactly why so many of these patients should get the typical ulcer in the typical situation just above the internal malleolus

A consideration of all these facts led us to investigate whether there was any local cause in the region of the ulcer to explain its origin This investigation fell naturally into five parts

(1) A clinical investigation to classify ulcers in the lower third of the leg (Cockett 1951) and to observe their natural history

(2) An anatomical study of the venous drainage of the subcutaneous tissues of the lower third of the leg and foot

(3) An anatomical study of the arterial supply of this same region

(4) Operations directed at excising the ulcer locally and investigating directly the condition of the veins in the immediate neighbourhood of the ulcer

(5) Venographic studies of the deep veins and veins of the ulcer-bearing area

This paper is concerned mainly with the results of the first four investigations

CLINICAL OBSERVATIONS

We tried to work out the earliest pathological change in the ulcer-bearing area—to discover the essential pathological change, in the subcutaneous tissues of the lower third of the leg, which predisposed to an ulcer The earliest and most constant pathological change we found was the presence of multiple small tortuous veins directly under the skin of the ankle region, often extending behind and below the malleoli Fig 1 shows such a case the dilated veins were confined to the ankle region, and there was no associated incompetence of the great or small saphenous systems This hæmangioma-like dilatation of all the small subcutaneous veins of the ankle region is a common sight in our varicose vein and varicose ulcer clinic and may be seen both in cases with dilated and incompetent superficial veins and in those without them When the ulcer first appears it seems to sit in the midst of this area of venous dilatation The ulcer itself is usually started by one of four things (1) local trauma followed by infection, (2) local eczema leading to scaling and infection, (3) bursting of one of the dilated varices in the area, leading to a hæmatoma, skin breakdown, and infection, or (4) thrombosis in one or more of these dilated venules

Once ulceration has taken place, local thrombosis, inflammation, and deposition of a plaque of hard fibrous tissue may rapidly hide the multiple subcutaneous venous dilatation in this area At this stage the ulcer appears to be in the midst of a hard plaque of indurated subcutaneous tissue, the classical induration of the lower third of the leg referred to by many authors However, in spite of this it can be seen that many of these ulcers appear to be superimposed on a mass of tortuous dilated veins, some partly thrombosed This has been confirmed many times venographically (fig 2)

Thus on clinical grounds alone there was evidence that some purely local venous incompetence might play a part in the ætiology of these ulcers

ANATOMICAL STUDIES OF VENOUS DRAINAGE

Our anatomical studies yielded some surprising results, confirming our suspicion that it was possible to have purely local venous valvular incompetence in the lower third of the leg Fig 3 shows a dissection of the superficial veins of the leg and foot It will be seen that, in the upper part of the leg just below the knee, the saphenous vein has several large branches (tributaries) draining the subcutaneous tissues of the upper part of the leg From the middle of the leg to just beyond the internal malleolus there are no branches Beyond the internal malleolus in the foot the saphenous vein breaks up into numerous branches draining the subcutaneous tissues of the foot and toes The numerous subcutaneous veins in the lower half of the leg on the inner side—the vital ulcer-bearing area—drain *not into the saphenous vein* but directly into the deep veins of the leg through three easily definable perforating veins

These perforating veins collect the venous drainage of this area, perforate the deep fascia, and empty directly into the posterior tibial venæ comites. They seem to be anatomically constant in position. There may be two, but more usually there are three of them, and usually one is much larger than the other two. Sometimes a small communicating vein passes from the saphenous vein to a branch of the lowest or middle perforating vein, but this is inconstant and may not be present (as in fig. 3). There is almost always a communicating branch between the saphenous and the highest perforating vein.

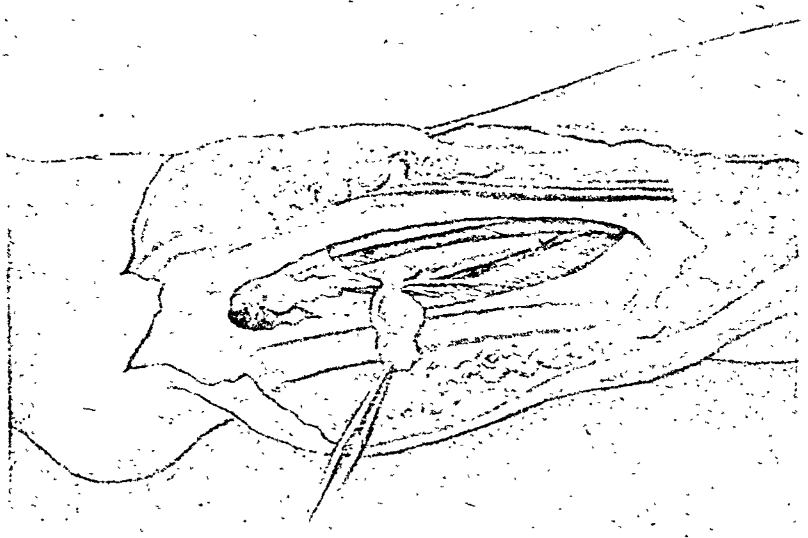

Fig. 4—Dissection of subcutaneous tissues of inner side of lower third of leg of a man who had had chronic varicose eczema of this region, without any saphenous incompetence. Deep fascia has been opened to show junction of large dilated incompetent middle *perforating vein with posterior tibial vein.* Note (1) vein passing from perforating vein, where it penetrates deep fascia, to soleus muscle; (2) great saphenous vein anteriorly; and (3) small dilated tortuous veins in subcutaneous tissues.

The three perforating veins penetrate the deep fascia in a line which corresponds to the space separating the soleus muscle from the deep muscles in the posterior compartment—i.e., a line which corresponds to the course of the posterior tibial vein. They are of such a size that they can easily be dissected out. The holes through which they penetrate the deep fascia have smooth edges easily felt with the dissecting scalpel; each one looks like a small saphenous opening in miniature. Usually one perforating vein enters each hole; this vein is usually formed as the junction of two main tributaries which collect the flow from the subcutaneous venous network. Each perforating vein is provided with a valve at its point of junction with the deep vein. This valve permits a flow of blood from superficial to deep veins, and thence upwards, but prevents reflux of the blood in the reverse direction. The competence of these valves is of supreme importance in the normal venous drainage of the lower part of the leg.

Figs. 3 and 4 show dissections of the whole region of these communicating veins in a normal leg (fig. 3), and in a case of chronic varicose eczema of the lower third of the leg in which the perforating vein was incompetent (fig. 4). A further interesting anatomical fact was shown: at the point where the perforating vein joined the posterior tibial venæ comites the venæ comites themselves communicated with each other, and a vein came directly from the soleus muscle to join the plexus. Thus at this point there was a miniature venous Piccadilly Circus. The possible significance of this muscle vein joining the plexus at this point is evident in cases of deep venous thrombosis, which usually starts in the deep muscle veins of the soleus.

Thus the venous drainage of the inner aspect of the lower third of the leg can be represented diagrammatically as in fig. 5, which shows venous drainage by two routes: (1) straight into the deep veins via the perforating veins; and (2) into tributaries which join the great saphenous vein just below the knee. Venous valvular incompetence may thus affect the lower third of the leg in two ways: (1) by valvular incompetence of either or both of the saphenous systems; and (2) by valvular incompetence of one or more of the perforating veins, the saphenous systems being intact. This latter type of incompetence, we believe, is of greater significance in the production of chronic ulcers and eczema of this region.

One further point must be emphasised. The existence of communicating veins between superficial and deep systems has been known for a long time. Excellent descriptions of the communicators in the lower third of the thigh and just below the knee have been given by Boyd (1948), Kinmonth and Robertson (1949), and

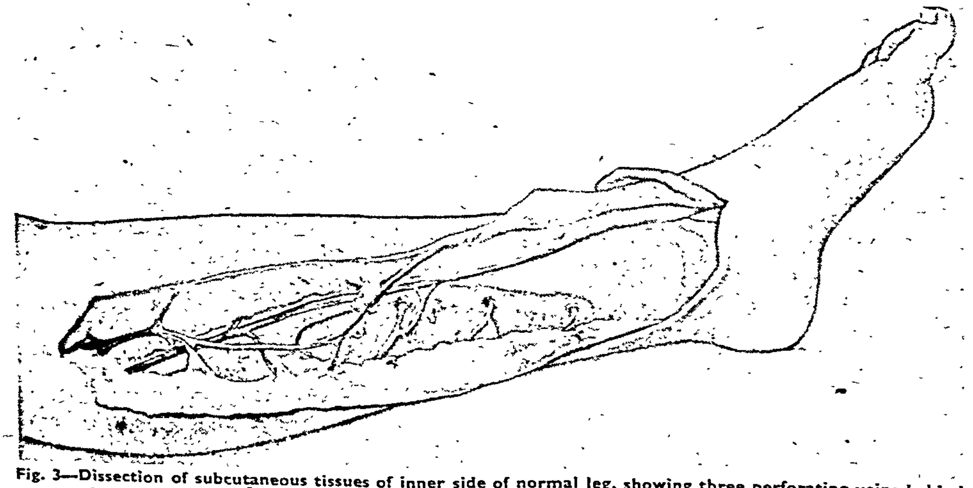

Fig. 3—Dissection of subcutaneous tissues of inner side of normal leg, showing three *perforating veins behind* great saphenous vein. Note (1) communicating branch between highest *perforating vein* and great saphenous vein, and (2) tributaries to great saphenous vein just below knee. Cf. fig. 5.

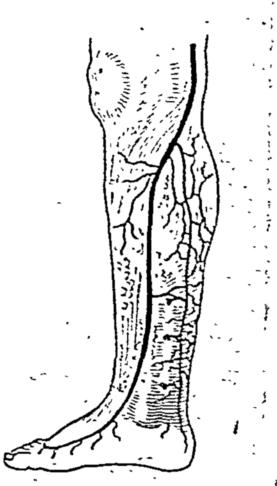

Fig. 5—Main venous drainage of inner aspect of leg.

others Surprisingly enough, little detailed work has been done on the communicating veins below the knee D A W Edwards (unpublished communication), by the injection of indian ink and plasma into amputated legs, has demonstrated that in the upper third of the leg there are numerous small communications between muscular veins and small subcutaneous veins The perforating veins described here differ from these in that they are large and constant in situation and drain directly into a large deep vein Moreover their situation is most significant they are situated just below a powerful muscle pump !

Thus on purely anatomical grounds it is probable that the great saphenous vein normally plays a minor part in the venous drainage of the subcutaneous tissues of the lower and inner part of the leg—the ulcer bearing area It drains the foot the upper part of the leg, and the thigh, and only through tributaries entering it at knee level does it contribute to the venous drainage of the ulcer-bearing area So it is not surprising that operations on this vein should often have little effect on many so called varicose ulcers

ANATOMICAL STUDIES OF ARTERIAL SUPPLY

A study of the arterial supply of the skin and sub cutaneous tissues of the leg and foot has been undertaken in conjunction with D A W Edwards The method has been to inject the arterial system of amputated limbs with bismuth suspension, and next to remove the skin and deep fascia completely in one layer This is then radiographed to give the arterial pattern The results of this investigation will be reported more fully elsewhere, but the main points are of significance in considering varicose ulceration, which is, after all, only a form of localised skin gangrene The arterial supply from knee to ankle comes from perforating arteries arising from the deep arteries directly and from the small muscular arteries These perforating arteries often accompany the perforating veins The density of perforating arteries is greater in the upper part of the leg than in the lower half, falling off considerably both in number and size when the ankle region is reached Below the malleoli the skin of the foot, particularly the heel, is well supplied with numerous large branches directly from the main vessels Thus from purely anatomical studies it is apparent that the skin and subcutaneous tissues in the lower third of the leg have relatively fewer small arteries, and that at the level of the malleoli there is a sort of arterial watershed—the foot below this level having a much more profuse arterial supply

EFFECTS OF INCOMPETENCE OF THE PERFORATING VEINS

The anatomical facts just given suggest that incompetence of the perforating veins draining the ankle would throw a very great strain on the venous mesh in the lower third of the leg which they drain This venous mesh is composed of delicate thin-walled veins which are not designed to stand up to a large venous pressure, unlike the thick muscular trunk of the great saphenous vein itself In the leg the valves are so arranged that the blood-flow is always from superficial to deep veins Every tributary of the deep veins is guarded by a valve at its entry, which ensures that no reflux from

This can be seen on the X-ray screen if 20 ml of 50% 'Pyelosil' is injected slowly into a small vein on the dorsum of the foot of a normal person in the prone position The opaque medium quickly appears in the deep veins of the leg, and within half a minute most of it is in the popliteal vein None can be seen in the superficial veins

The mechanism for returning venous blood from the limb in the erect position is well known The deep fascia of the leg forms a firm investing layer enclosing the large muscles of the calf When these contract within the firm inextensible sheath of deep fascia they squeeze venous blood out of the leg with considerable force Barcroft and Dornhorst (1948) have shown that this calf muscle pump can overcome a resistance greater than 100 mm Hg The valves of the veins are so arranged that the blood can leave this pump only in an upward direction Now, the perforating veins which drain the ankle pass through small holes at the bottom of this powerful pump When the pump contracts, there is, in the veins below the pump, a momentary reflux of blood downwards as far as the valves This can be seen excellently in a post-mortem dissection When the perforating vein has been dissected out, the calf is suddenly squeezed the blood, which is still fluid in the deep veins, is forced towards the perforator but is suddenly held up by its valve

Now, if this valve should become incompetent or be damaged in any way, at every contraction of the calf pump the increase in venous pressure within it would be transmitted downwards and outwards through the incompetent perforating vein to the thin venous mesh above the internal malleolus This would in time lead to dilatation and tortuosity of this mesh, and this would mean stagnation of venous blood in it As we have seen, this is exactly what was seen to happen in ulcer patients from clinical observation alone We have observed every stage from a pre ulcer state, which consists of merely a large mesh of dilated venules round the ankle (fig 1), through thrombosis in this mesh, to a fully developed ulcer sitting on a fibrotic mass or plaque Thus we believe that the genesis of many so called varicose ulcers can be shown diagrammatically as in fig 6

We were fortunate to find at necropsy a man, aged 56, who had had chronic eczema of the lower third of the leg for many years but had not undergone operation, because no varicose veins were visible Fig 4 shows a drawing of the dissected leg The whole of the sub cutaneous tissues in the affected region were full of small tortuous dilated venules, many of which were

thrombosed, with considerable fibrosis round them, making them feel like an indurated plaque to the examining fingers. This seems to be the essential pathology of the pigmentation and induration so often seen in the stasis syndrome of the lower leg. These dilated vessels were draining directly into one large incompetent perforating vein, which is well shown in the figure and was the middle of the three perforating veins described. The fully dissected and mounted specimen of this incompetent perforating vein is shown in fig. 7. The effect of this local valvular incompetence is well seen on comparing it with the dissected and mounted specimen of a normal perforating vein (fig. 8).

OPERATION FINDINGS AND RESULTS

If this explanation of varicose ulceration is true, it should be possible to find these incompetent perforating veins, and, by tying them at their point of passage through the deep fascia, cut off the source of local venous incompetence, thus applying the principle of the Trendelenburg operation to the lower third of the leg.

The presence of incompetent perforating veins may be suspected in the following circumstances:

(1) A varicose ulcer has not healed, or has recurred, after an efficient surgical obliteration of incompetent veins of the great saphenous system.

(2) Ulceration or induration and pigmentation of the lower third of the leg is present without evidence of saphenous incompetence.

(3) A mass of small dilated varices is present in the lower third of the leg, with or without incompetence of the saphenous vein.

Very occasionally the incompetent perforating vein can be seen as a localised bulge in the lower third of the leg; but this is rare and has been seen and confirmed at operation only twice by us. Most of these local "blow-outs" in the course of a varicose vein are simply local aneurysmal dilatations of the vein wall and do not mark the points at which perforating veins pass through the deep fascia.

In most cases the incompetent perforating vein which is the root of the trouble cannot be seen or felt, because it is very effectively covered by a plaque of indurated tissue consisting of the numerous minute thrombosed venules embedded in fibro-fatty tissue. This is probably why their importance has not been fully appreciated: they are the nigger in the woodpile—the woodpile being the ulcer and plaque of induration.

Figs. 9 and 10 show a typical incompetent perforating vein of the ankle exposed at operation. Fig. 9 shows the site and extent of the incision necessary. Fig. 10 is a close-up of the perforating vein showing the round hole in the deep fascia (exactly comparable to the fossa ovalis) through which it comes, and its relation to the great saphenous vein at the ankle.

This operation involves cutting and dissecting in an area of devitalised skin and one might expect that necrosis and breakdown of the incisions would follow. It has been our practice to excise not only the incompetent perforating vein but also as much as possible of the subcutaneous plaque of thrombosed venules and fibrous tissue, and the ulcer itself if one is present. The resulting defect is left to granulate for a few days and is then grafted with a split-skin graft. There has been no difficulty about these grafts taking. In some of the other cases in which there has been no ulcer but merely a patch of early eczema or pigmentation this has not been necessary, and the skin edges can be brought together quite well and heal. Provided the cause of the poor vitality of the skin—i.e., the incompetent perforating vein—is found and removed at operation, satisfactory

Fig. 8—Dissected and mounted specimen from normal leg (cf. fig. 7). A valve was present where perforating vein joined deep vein, and valves were present in all other veins.

healing will take place However, a good deal of caution must be exercised in dissecting in this area, and we have had one case in which the edges of the incision broke down In general, if an ulcer is present, the indurated plaque, and the incompetent perforating vein should all be excised in one piece, as was done in case 1 (see below), and the area should be grafted If there is no ulcer, as little dissection as possible should be done, but the area of the perforating veins should be approached directly through a longitudinal incision placed slightly behind the internal malleolus (fig 9) The tissues are then divided straight down to the deep fascia, at which plane a gentle search is made for the perforating vein The perforating vein which is most often incompetent, in our short experience so far is the middle one of the three and is situated a hand breadth above the internal malleolus

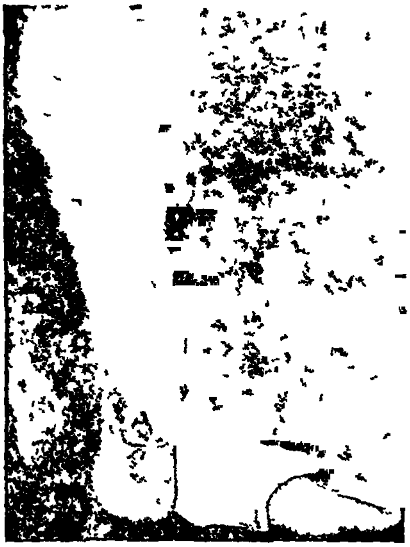

Fig 11—Leg of case 1 before operation note (1) scars of previous operation for tying veins, and (2) great saphenous vein well anterior to ulcer Cf figs 13 and 14

There is considerable variation in the branches (tributaries) of the perforating veins, and in the way in which they communicate with the great saphenous vein But the foramina through which they penetrate the deep fascia are remarkably constant in these positions, and it is for this reason that a standard surgical approach can be made to them

The following is a summary of two cases followed up for nine months and one year respectively

Case 1 —A housewife, aged 57, had had a varicose ulcer of the left leg for fifteen years Fig 11 shows its size and situation There was no definite previous history of deep thrombosis Four years previously she had had a Trendelenburg operation and below knee excision of her varicose veins The ulcer healed for about six months after this operation but then recurred As her below knee veins were still prominent, she was readmitted in October, 1951, and two more fairly large below knee veins were dissected out Again the ulcer healed, but only for a month this time when it recurred again and was as big as ever Venography was then done, and a large perforating vein was seen, connected to a tortuous vein going straight down to the ulcer area (fig 12)

In April she was readmitted to hospital, a lumbar sympathectomy was done to ensure full skin vasodilatation of the ulcer area,

Fig 13—Leg of case 1 three days after opera-

the perforating vein was exposed and divided, and its large tributary leading from the ulcer, and the ulcer itself, were excised in one piece Fig 13 shows the leg two days after this operation The defect was grafted with split skin four days later The skin graft took very well, and fig 14 shows the patient's leg six months later For the first time in fifteen years she can walk about without supporting bandages The area formerly occupied by the ulcer has consolidated and shows no signs of breaking down

Case 2 —A policeman, aged 42, had a small chronic ulcer as large as a shilling about a hand breadth above the internal malleolus It had been present for a year and a half and had resisted all attempts to heal it The venous and arterial systems in the leg were normal, but just underneath the ulcer was a small bunch of dilated veins Venography showed a normal venous system, except that in this region an enlarged and tortuous perforating vein was seen joining the deep vein At operation the ulcer, which had closed in considerably on energetic supportive treatment, was excised, and the underlying dilated perforating vein was found and ligated at its point of penetrating the deep fascia The skin could be brought together easily with a little undermining of the edges Healing was satisfactory, and there was no recurrence nine months later, when the patient was last seen No bandage of any sort has been worn

The follow-up of our cases has so far been too short for us to come to any definite conclusions about the efficiency of the operation in preventing varicose ulceration or in curing established ulceration Since becoming aware of the existence of these incompetent perforating veins in the anatomical situation described we diagnosed them and found them at operation in 10 cases, in 3 other cases we failed to find the incompetent perforating veins we expected to find

The early results have been gratifying, the skin has healed, the spray of dilated veins has disappeared, and the few early ulcers we have treated have not shown any signs of recurrence Only in 1 case, already referred to, did the skin break down This was due to our operating through an area of skin which had been in the active eczematous stage too recently, and the wound became infected

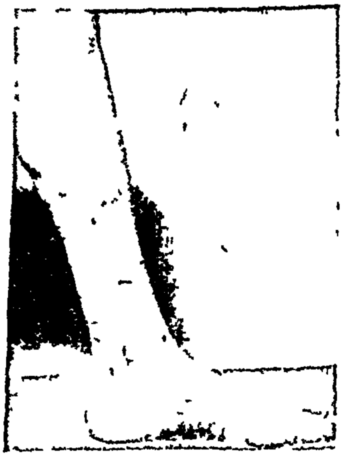

Fig 14—Leg of case 1 six months after operation

DISCUSSION

In the most recent editions of *Gray's Anatomy* (Johnston and Whillis 1951) and *Cunningham's Anatomy* (Brash 1951) the venous drainage of the lower third of the leg is described without any reference to these perforating veins, nor are they shown in any of the illustrations Grant (1951) shows them accurately but does not mention them in the text Thus their anatomical existence and importance do not seem to be widely appreciated

Their importance in the venous drainage of the subcutaneous tissues of the lower third of the leg—the ulcer bearing area—is considerable Many observers—e g, J R Learmonth and L G Higgins (personal communications), Foote (1952), and Dodd (1952)—have noticed the presence of these large perforating veins at operation near ulcers or directly under ulcers, but, so far as we know, these clues have not led to any detailed anatomical study Foote (1952) has advocated operating on them when they are seen, and American workers particularly Linton and Hardy (1948) and Merle Scott (1951), have for some time been convinced that the true cause of many cases of ulcer of the leg lay in incompetence of many communicating veins in the lower leg. Linton's operation of stripping the deep fascia is based on this theory. Merle Scott (1951) has designed an aeropulse legging for fitting on the lower leg, whose design is based on this assumption. However, the fact that the perforating veins usually responsible for the ulcer syndrome are so large, easily accessible, and so anatomically constant in the sites where they pierce the deep fascia has not so far been recognised. Armed with this basic knowledge a planned operation can be performed on them, as accurate as the standard Trendelenburg procedure and based on exactly the same principle.

It now becomes possible to understand why ulcers should develop after a deep thrombosis. For, if there is a block in the deep veins of the leg due to thrombosis, surely the main alternative path for the return of venous blood is outwards through these, and the many other small, perforating veins (the reverse of the normal flow) and up the superficial veins. This means breaking down the resistance or destroying the valves in the perforating veins. Once this thrombosis has settled, and the collateral venous channels have formed and enlarged, the leg is left with the condition which we have shown may lead to ulceration—i.e., incompetent perforating veins below the calf pump. Thus the reason for the development of these ulcers becomes intelligible, and a clue to their early treatment is provided.

Moreover, the anatomical arrangement whereby a vein from the soleus joins the posterior tibial venæ comites at the same point as the perforating vein enters gives the clue to how the valves in the perforating veins may be destroyed. In the man whose leg is depicted in fig. 4 (who died from pulmonary embolism), the large incompetent perforating vein contained an antemortem clot which extended inwards and was continuous with a similar clot in the muscle vein going to the soleus. The veins in the soleus were full of antemortem clot. Thus it seems that here we have an anatomical pathway whereby clot from the deep veins in the soleus may spread out to the superficial veins of the ankle region via the perforating veins. A localised area of induration and redness, apparently a local patch of superficial thrombophlebitis, in the ulcer-bearing area is a common precursor of an ulcer or eczema—and this is probably the mechanism of its occurrence. Such cases usually show calf tenderness as well. It is well known that the organisation of clot in veins will destroy the valves; so here is one possible way in which the valves of the perforating veins may be destroyed after deep thrombosis.

Thus there is reason to believe that incompetence of these perforating veins may be the cause of many post-thrombotic and so-called varicose ulcers. We have therefore called this condition the "ankle blow-out" syndrome to differentiate this particular type of venous incompetence in the lower leg leading to ulceration and eczema from the more generally recognised saphenous incompetence.

SUMMARY

The anatomy of the venous drainage and arterial supply of the inner aspect of the lower third of the leg is described.

The constant anatomical situation of three perforating veins in this area is described, and the effects of valvular incompetence of these veins situated below the calf muscle pump are discussed.

Criteria for the diagnosis of incompetence of these perforating veins are suggested.

An operation aimed at tying these incompetent perforators where they penetrate the deep fascia of the calf is described. The principle of this operation is exactly similar to that of the generally accepted Trendelenburg operation.

The name "ankle blow-out" syndrome is suggested to differentiate this type of venous valvular incompetence from the more generally recognised saphenous incompetence.

We wish to acknowledge the painstaking assistance of Mr. F. R. Scholefield in dissecting and mounting the specimens. The help of Miss J. Dewe with the drawings and of Mr. K. Moreman with the photographs is also gratefully acknowledged, and of Miss F. Hunter with the secretarial work. We should also like to thank the sisters and nursing staff of the Royal Waterloo Hospital for their coöperation and care for the patients.

ADDENDUM

Since this paper was written we have had a further 20 cases in which one or more large incompetent "blow-outs" have been found and tied at operation. In most of these cases the blow-out was either just above or immediately under an early ulcer or area of devitalised skin. The constant anatomical situation of these foramina where the veins perforate the deep fascia has been repeatedly confirmed.

LIGATION OF THE POPLITEAL VEIN FOR THE GRAVITATIONAL SYNDROME

H. D. MOORE
M.C., M.B. Sydney, F.R.C.S., F.R.C.S.E.
SURGICAL TUTOR, GENERAL INFIRMARY, LEEDS

With illustrations on plate

Bauer (1948) investigated the deep veins of the legs by venography and by measuring the pressure in the popliteal vein. He found that patients with the gravitational syndrome had no demonstrable valves in the deep veins and no fall of pressure in the popliteal vein when it was occluded below the point of measurement; whereas in patients without leg symptoms the valves were always shown and the pressure always fell. Bauer therefore concluded that the syndrome was the result of an unsupported column of blood in the deep veins extending from the heart to the feet, and that this column should be broken by ligation of the popliteal vein. His results in a large number of cases were excellent (Bauer 1950).

Reports from other surgeons, however, are few and on the whole not impressive. Castagna and Impallomeni (1951) state that ligation of the popliteal vein was first practised by Parona in 1904, but that his results were not good, probably because the cases were ill chosen. The operation was abandoned except by a few surgeons, such as Giordano (1934, 1937), who had success in some cases. Castagna and Impallomeni (1951) reported 20 cases with good results after a month, of which 16 were followed for three months and were still satisfactory. De Takats and Graupner (1951) operated on 10 cases, of which 7 were successful but were only followed for a very short time.

The following cases are therefore reported Though the numbers are small (23 legs in 18 patients), they have been followed long enough to give a reasonable idea of what is likely to happen, and to enable an opinion to be formed on the value of the operation

The gravitational syndrome is characterised by aching of the legs, by a brownish discoloration and induration of the front (sometimes the whole) of the lower leg, with swelling of the ankles towards the end of the day, and by ulceration in the malleolar region or front of the lower third of the limb It may or may not be associated with varicose veins, and there is often, but by no means always, a history or venographic evidence of a previous deep venous thrombosis

The cases described here fall into three groups

Group 1 —Those suffering primarily from ulceration of the lower leg, and only secondarily from discomfort, aching, and swelling

Group 2 —Those in whom the chief complaint was of considerable aching (what has been described as a bursting feeling) and swelling of the ankles and legs, but who complained also of the discoloration and induration already described In this group there were no actual ulcers at the time of operation it was the aching which brought them for advice

Group 3 —Those with swelling of the legs considered to be of venous origin These patients complained of aching and discomfort also, but the swelling was the chief complaint

They had all been given the usual treatment of pressure dressings of one sort or another, from elastic stockings to 'Viscopaste,' without success Many had had superficial veins injected, where visible, but without improvement, and all were a good deal disabled (fig 1)

The method of selection for operation was venographic —i e, patients in whom no valves in the deep veins could be demonstrated by ascending venography (Moore 1949) were considered suitable for ligation of the popliteal vein The venographic appearances, apart from the lack of valves, were of two kinds, the veins being either irregular, "moth eaten" and small, owing to old thrombosis and recanalisation (fig 2), or smooth and often larger than normal (fig 3), an appearance commonly, but by no means always, associated with a history of "white leg" The differences in appearance can more readily be appreciated by comparing them with the normal (fig 4*a*)

RESULTS

Group 1 (13 legs in 11 patients) —The ulcers have completely healed, with no swelling or discomfort, in 9 of the legs (7 patients), the longest time since operation being three years, the shortest nine months, and the average just under two years

One patient, followed for nearly three years, has complete relief from pain and swelling in the legs, although the ulcers did not heal

3 patients, all operated on more than two and a half years ago, have shown no improvement, but they have not been made worse by the operation

Group 2 (7 legs in 5 patients) —There was complete relief of discomfort in all of them and, surprisingly enough, the swelling was less or completely cured The longest time since operation is two and a quarter years, the shortest a year, and the average over eighteen months

Group 3 (3 legs in 2 patients) —I decided to try the effect of popliteal ligation in this type of case, where the swelling seemed to be of venous and not lymphatic origin, because my previous experience had shown that the swelling of the legs usually improved after ligation of the popliteal vein Only 2 cases have so far been operated on, but they are perhaps worth describing

Case 1 —A man, aged 36, complained in October, 1945, of three months and the swelling decreased Three months later the leg was worse again, and he was again in hospital for eleven weeks This swelling and partial recovery had continued since then, making his work as a miner impossible

On examination in September, 1950, the leg was extremely swollen and tight, for which no cause was found except grossly abnormal deep veins of the left leg, shown by venography (fig 4*b*), those of the right being normal (fig 4*a*) Ligation of the deep veins was thought to be justified

At operation in October, 1950, two large veins were found in the popliteal space, one being macroscopically normal and the other thrombosed and adherent to the sciatic nerve An inch of each vein was excised The leg steadily improved after operation

Right Leg —In December, 1950, the same course of events began in the right leg the swelling started in the foot and in about a week spread to most of the right leg Under treatment with anticoagulants it improved rapidly but in January, 1951, it again became severely swollen This time it improved with rest in bed However, in April, 1951, it was once more very swollen The venogram (fig 4*c*) now showed gross abnormality of the deep veins of the right leg The right popliteal vein was tied, and a right Trendelenburg operation was done

The condition gradually improved for two to four months and by February, 1952, there was slight swelling only in the right leg, the left being normal The patient had returned to work as a miner

Case 2 —A woman, aged 46, had two and a half years' history of persistent swelling of both legs without obvious cause The swelling improved with rest in bed In April, 1952, the left popliteal vein was tied It is too soon to say whether there will be any improvement, but the operation has not made the condition worse

DIFFICULTIES ASSOCIATED WITH OPERATION AND REASONS FOR FAILURE

It was not realised at first that (contrary to Bauer's experience) the ulcers were not going to heal spontaneously after ligation of the popliteal vein, but it soon became evident that rest in bed and skin grafting were necessary to achieve this The method now used is to put the patient to bed and to treat the ulcers with streptomycin locally for a few days and then to apply a thin split-skin graft, which takes very well As soon as the ulcer is covered, the popliteal vein is tied, about an inch of it is excised, and the patient is encouraged to be up and about The following two cases illustrate this very well

Case 3 —A woman, aged 56, was seen in December, 1948 She had had ulcers on the lower part of the left leg for fourteen years and on the right leg for four years At the age of 9 she had had a severe injury to the left foot, which became infected, and she was in hospital for a year She had been treated by support (viscopaste, &c) for eighteen months before coming under my care, but without improvement

On examination both legs were thin and without visible veins The lower third of each leg was discoloured, indurated, and ulcerated (fig 1), and there was a severe equinous deformity on each side The arterial supply to the legs seemed normal, but the feet tended to be cold and sweaty Venography showed deep veins which had been thrombosed and recanalised (fig 1)

Treatment —Left lumbar sympathectomy in January, 1949, improved the ulcers on the operated side but did not cause them to heal The ulcers on the right side also improved to some extent In May, 1949, the left popliteal vein was tied and the patient was discharged, with viscopaste support, before the ulcers were healed In January, 1950, the ulcers being still unhealed, the right popliteal vein was tied and skin was grafted on the ulcers on both legs The grafts were successful the ulcers healed on both legs and have remained healed

Case 4 —A woman, aged 67, had recurrent ulceration of the right leg for eight years There was no history of "white leg" and histology of the popliteal vein showed nothing to indicate a past thrombosis No varicose veins were seen On

Trendelenburg operation was done at the same time. The patient was kept in bed for a week and then discharged with supporting dressings, but with the ulcers unhealed. During the rest in bed the ulcers improved, but this improvement ceased as soon as she became ambulant. She remained in bed for a month at home, but still the ulcers did not heal. On Jan. 25, 1950, skin was grafted on the ulcers without preparation and this proved only partly successful. On Jan. 31 local treatment with streptomycin to the ulcers was begun, and on Feb. 8 more skin was grafted. On Feb. 21, 1950, the ulcers had soundly healed, and the patient was discharged. The ulcers have remained healed.

This failure to heal without grafting is probably the cause of the partial failure in the one case which improved but did not heal, for this patient resolutely refused to remain in hospital until the ulcers healed and as resolutely refused to return for further treatment.

The scar in the popliteal fossa has caused some discomfort in 3 patients, with keloid formation, but has proved no real disability. In 1 patient, however, the scar has persistently broken down, although the ulcers, for which the operation was done, have remained healed. This patient has angina pectoris and arterial deficiency in the affected leg; this may be the cause of the trouble with the popliteal scar. It would perhaps be better to make a lateral incision to tie the popliteal vein.

The 3 cases which failed to improve were all in group 1, with ulceration. 2 of them subsequently showed definite arterial deficiency, which was not recognised at the time although looked for, and later healed after sympathectomy; Bauer (1950) has had similar experiences. The 3rd case showed venographically (fig. 5) and at operation a complete block of the upper end of the popliteal vein. It is therefore hardly surprising that no improvement took place—this was a complete error of judgment.

CONCLUSIONS

It seems reasonable to conclude that the operation does no harm, and that in suitably chosen cases it can relieve the patient of symptoms for a considerable length of time.

Most of the patients have continued to wear elastic stockings, but a few have discarded all forms of support and have remained symptom-free.

SUMMARY

23 legs have been treated for the gravitational syndrome by ligation of the popliteal vein.

Complete relief of symptoms has been obtained in 18 and improvement in 1; 3 have shown no change, and 1 is too recently done to judge.

The longest time since operation, in those with a good result, is three years, the shortest time nine months, and the average just under two years.

The patients selected for operation were those in whom no valves could be seen in the deep veins by ascending venography.

The importance of healing the ulcers before discharge from hospital is emphasised.

The value of the operation for œdema of venous origin is discussed.

I wish to thank Mr. D. A. Abernethy, senior surgeon to the Radcliffe Infirmary, Oxford, and the members of the staff of the General Infirmary at Leeds, who very kindly permitted me to treat their cases.

ADDENDUM

Since writing the article, 1 leg in group 1 has broken down after remaining healed for two years and two months. This is the patient referred to later in the article who had had much trouble with the popliteal scar, together with arterial deficency in the legs. Sympathectomy has not improved matters.

In group 3, case 2 has not improved over a period of eight months, but is no worse.

Therefore, of the 23 legs, 17 have complete relief of symptoms and 1 is improved; 1 ulcer was healed for two years and two months but has relapsed; 4 legs are unchanged.

MELORHEOSTOSIS

R. A. Trevethick
M.B. Sheff.
WORKS MEDICAL OFFICER, STEEL, PEECH & TOZER LTD.

With illustration on plate

Up to 1948 only four cases of true melorheostosis (Léri type of osteopetrosis, or *osteosi eburnizzante monomelica* of Putti) had been reported in this country (Fairbank 1948), and no further case has been recorded here since. Hess and Street (1950) have reported one in America, and Thompson et al. (1951) one in South Africa.

CASE-RECORD

In March, 1952, a healthy male, aged 19, complained of pain in his left knee after pulling on a rope.

History.—On four previous occasions he had had similar sudden pain in one of his other limbs after strenuous activity. In November, 1950, his left arm was the site of pain which subsided after treatment with lead and opium. In March, 1951, while he was playing football, something "went" in his right knee: there was no effusion; movement remained full; the anteromedial compartment was tender; and the condition cleared up in a week under treatment with a U-pad and bandage. In May, 1951, while pulling on a chain at work, he experienced sudden pain at the back of his right shoulder: strain of the serratus posticus muscle was diagnosed and was cured in a week with infra-red therapy. In November, 1951, again while pulling on a chain at work, he felt a sudden pain in his right wrist: the tendon of the extensor pollicis longus was found to be tender and the wrist was strapped with 'Elastoplast' and cured in a week.

At the age of 4 years he had had pneumonia, followed by an operation on his left foot. A subastragaloid arthrodesis had been performed.

On examination the left leg was 2 in. shorter than the right. The left foot was fused at the subastragaloid joint, with the forefoot fixed in inversion, and almost rigid claw toes. The left quadriceps was in good condition. A large hard mass, not attached to the skin, lay posterior to the internal collateral ligament of the knee-joint, and a smaller soft cystic swelling lay medial to the patella. There was no effusion into the joint. Extension 180°, flexion 80°. Slight lateral mobility of the joint, but no laxity of the cruciate ligaments. The skin of the leg was quite normal.

Radiography showed a dense mottled sclerosis of the femur, patella, tibia, and astragalus of the left leg. All the changes were on the medial side of the bone and densest near the hip, knee (see figure), and ankle. There were dense lines of sclerosis along the medial sides of the shafts of the long bones of the left leg. No bony lesions were found in other parts of the skeleton.

The radiological appearances around the joints are typical of melorheostosis, but the straight lines of sclerosis in the shafts of the femur and tibia present a similar appearance to osteopathia striata rather than the candle drippings of melorheostosis. In view of the distribution of the bony changes—which are confined to one side of one lower limb—this must be regarded as a case of melorheostosis.

SUMMARY

A case of melorheostosis in one lower limb of a young male is described

The main complaint was pain, though there was slight limitation of movement There were no skin changes The patient was able to do his job and play football without difficulty

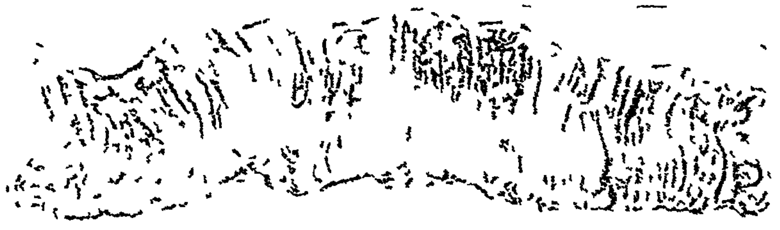
NECROTIC JEJUNITIS WITH PERFORATION

J P Herdman
B M Oxfd, F R C S
SENIOR REGISTRAR, OXFORD UNITED HOSPITALS

Necrotic jejunitis is a non specific acute inflammation of the upper part of the small intestine, which may proceed to perforation or to hæmorrhage It has been reported in epidemic form in Germany (Fick and Wolken 1949) and, under the name of non-specific ulcer of the small intestine, in isolated cases in the United States (Ebeling 1933, Evert et al 1948)



Operation specimen

The following case, which presented as a general peritonitis, seems to be the second reported in this country The first was described by Young (1949)

CASE-RECORD

A woman, aged 60, was admitted as an emergency on Jan 26, 1952 She had had upper abdominal discomfort after meals for the previous four months, and had lost about a stone in weight Twenty two hours before admission she had been seized with a sudden very severe generalised continuous abdominal pain, and she had vomited several times She had not passed flatus since the onset of the pain

On examination she presented the typical appearance of general peritonitis Her temperature was 100°F and pulse rate 108 Her abdomen was rigid, and bowel sounds could not be heard General peritonitis was diagnosed

Laparotomy —The abdomen was opened through a right paramedian incision The peritoneal cavity contained much foul smelling purulent free fluid A loop of jejunum 9 in long about 4 ft from the duodenojejunal flexure was œdematous and covered with flakes of fibrin The remainder of the jejunum and the ileum was normal, apart from a few jejunal diverticula on the mesenteric border There were no diverticula in the thickened segment of intestine A small hole was found in the mesenteric border of the jejunum through which jejunal contents could be squeezed The affected segment of jejunum was excised, and an end to end anastomosis made

Convalescence —The patient made a good immediate recovery from the operation, but her convalescence was delayed by a pulmonary embolus on the eighth postoperative day, this was treated with anticoagulants She was discharged from hospital on the thirty second postoperative day

Investigations —A swab taken from the peritoneal cavity at operation contained pus cells but no organisms Culture on blood agar was sterile Agglutination was negative to salmonella and brucella groups A fractional test meal gave normal results No pathogens were isolated from the stools. Radiography after a barium meal fourteen days after operation showed that the second part of the duodenum was dilated, and the third part curled on itself Stasis was present, and there was irregularity of the mucosa of the distal duodenum and proximal jejunum, together with some filling defects compatible with ulceration

Operation Specimen —The excised segment consisted of a portion of jejunum 25 cm in length and bearing several ulcers, the largest being 1 3 cm in diameter (see figure) The ulcer bases were occupied by necrotic material infiltrated with many polymorphs and with histiocytes Between the ulcerated areas all layers of the jejunal wall were congested and infiltrated with plasma cells and polymorphs In the areas of ulceration necrosis and inflammation extended down to the serosa and at one point seemed to have perforated the gut wall

COMMENT

The ætiology of necrotic jejunitis is unknown It has been suggested that *Clostridium welchii* type F may be responsible (Zeissler and Rassfeld-Sternberg 1949) but in the present case neither this nor any other pathogen was isolated from the stools Necrotic jejunitis does not seem to be related to Crohn's disease Simple closure of the perforation has been suggested as the best form of treatment, but, in view of the extent of the process, resection and end-to-end anastomosis are preferable

Radiography fourteen days after operation showed well marked changes in the remaining part of the upper small intestine The patient had had symptoms of dyspepsia for some months before her jejunal perforation, so it should probably be possible to diagnose necrotic jejunitis by radiography before perforation or hæmorrhage brings the patient to hospital as an emergency

My thanks are due to Mr A Elliot Smith for allowing me to undertake the care of this case, to Dr *W S Holden for the radiological report, and to Dr H* Kramer for the pathological report

SUPPURATIVE ARTHRITIS IN THE AGED

R D Blachford
M D Lond, M R C P
CONSULTANT PHYSICIAN, SELLY OAK HOSPITAL, BIRMINGHAM

Degenerative disease is so often found in the aged that its presence is apt to be assumed by the physician This assumption leads easily to the further assumption that, if it is possible to explain any symptom in an old person in terms of a degenerative process, that explanation will probably be correct

Though it cannot be denied that these assumptions approach the truth, probability is not certainty, and various diseases masquerade as arteriosclerosis, cerebral thrombosis, cardiac failure, &c

Within a comparatively short time three such cases have come to my notice In each the development of pain and uselessness of an arm led to the diagnosis of a "stroke," and in each the shoulder-joint was eventually found to be full of pus I cannot find any specific reference to this condition in the aged, but it may well be commoner than is imagined and it illustrates the ease with which a large collection of pus can be missed at this time of life

CASE RECORDS

Case 1 —A man, aged 87, had been seized with pain in his right shoulder while sawing wood four days before admission The pain had become worse and was very severe A stroke had been diagnosed

On examination there was a tense effusion in the right shoulder joint, causing great pain on moving the right arm The patient was obviously very ill Radiography of the shoulder showed only an old united fracture through the tip of the right acromion.

Treatment and Death.—The shoulder lesion was thought to be traumatic, and the arm was immobilised, but the patient died three days later.

At necropsy there was about a pint of pus in and around the right shoulder-joint, from which a pneumococcus was grown. No bone abscess was found. Bronchopneumonic changes were found in both lungs.

Case 2.—A man, aged 78, gave four weeks' history of cough, sputum, and pain in the right upper chest. At the same time he had developed weakness of the right arm. His doctor reported that earlier in the illness he had had a temperature of 100°F and signs of bronchitis.

On examination on the day after admission he did not appear very ill. There were signs of consolidation over the upper lobe of the right lung and an effusion into the right shoulder-joint. Pain was not conspicuous, and the first comment on the arm in his hospital notes is "right arm paralysed and spastic." The only other significant finding was extensive dental sepsis. A white-cell count showed 7500 per c.mm. (polymorphs 59%, lymphocytes 26%, monocytes 14%, Türck cells 1%).

Surgical advice was sought, but the patient died suddenly and unexpectedly next day.

At necropsy there was pus, from which no organisms were grown, in and around the right shoulder-joint. The right subclavian vein was thrombosed, and fragments of ante-mortem clot were scattered throughout the branches of the right pulmonary artery, the upper lobe of the right lung being partially consolidated through infarction, without any evidence of suppuration. This condition seemed to have been present for some days. A large recent embolism in the right pulmonary artery was thought to be the cause of death. There was no evidence of pneumonia.

Case 3.—A woman, aged 69, had been diabetic for nine years, and had had a penetrating ulcer on the second right toe for two months. Six weeks before admission she became bedridden through pain and uselessness of her right arm. A stroke was diagnosed.

On examination she was drowsy but conscious, and her urine was loaded with sugar. Her blood-sugar level was 230 mg. per 100 ml. Her knee-jerks and ankle-jerks were absent, and an ulcer on the dorsum of her right second toe had penetrated into the first interphalangeal joint. An effusion into the right shoulder-joint caused considerable pain on movement of the arm. Aspiration of this effusion produced thick pus, from which a coagulase-positive *Staphylococcus aureus* was grown. A white-cell count showed 6000 per c.mm. (polymorphs 87%).

Treatment and Death.—The patient remained afebrile but, despite systemic and intra-articular penicillin, died after eight days

At necropsy the right shoulder-joint was full of pus, which had also tracked among the shoulder muscles. No abscess was found in the bone.

DISCUSSION

Apart from gonococcal disease and penetrating wounds of the joints, suppurative arthritis is usually pneumococcal or associated with osteomyelitis, when it is usually staphylococcal. Of 248 pneumococcal cases 16% were in the shoulder, and of 187 patients 10 were aged more than sixty-five (Bulkley 1914, Keefer et al. 1934, Bloomberg 1935, Eggers 1936, and Blankenhorn and Grupen 1943). Of the cases associated with osteomyelitis the combined figures of Bisgard (1932), Wilensky (1934), and Blaisdell and Harmon (1942) give an incidence of 8·5% in the shoulder. In Blaisdell and Harmon's series, where age is stated, 2 out of 57 patients were aged more than sixty-five, and these workers comment that in adults arthritis tends to appear rather than osteomyelitis. A similar comment is made by Leavitt (1940). These data tend to show that among suppurating joints the shoulder is not a rarity and that it has been observed in the aged (Blankenhorn and Grupen's oldest patient was aged ninety).

As regards the source of infection in the present cases, it seems clear that the toe was responsible in case 3. In case 1 the lungs seem most likely. It is, however, hard to believe that the old man was sawing wood with an established pneumonia. Since the changes found in the lungs post mortem were no more than those expected in one who has spent four days dying, perhaps the primary lesion was a bronchitis. In case 2 there were two possible sources—the teeth and the lungs. Unfortunately the organism is unknown, and further speculation is futile.

CONCLUSION

I do not suggest that joint suppuration is a common cause of uselessness of the arm. My point is that such suppuration can occur in aged people and can be missed; and that, when a swollen painful joint occurs in such a patient, the presence of pus should be seriously considered.

SUMMARY

Three cases of suppurative arthritis of the shoulder-joint in aged persons are described.

In each the first diagnosis was a stroke.

All were fatal.

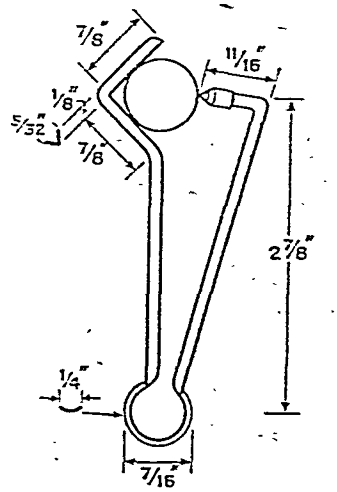
DIAMOND-TIPPED AMPOULE CUTTER

SEALED ampoules containing reagents or medical preparations are generally opened by scratching the glass of the neck with a file and snapping it off. It is often difficult to make a suitable scratch with a file on an ampoule containing liquid, owing to one's natural hesitancy towards applying any force to such a container. In addition, a file scratch often produces a jagged cut which is not only a menace to the operator but also may produce glass splinters which fall into the solution. A file rusts and is difficult to keep clean. A simple ampoule cutter, provided with a diamond point, has been designed to overcome these disadvantages of a file.



The cutter can be readily made at any diamond-tool shop by bending 18-gauge stainless-steel strip into the shape illustrated, and brazing a small diamond on to the point as in making a glass cutter. The diamond need only be ½ carat, and should preferably be a sharp-pointed octahedron. Unlike the glaziers' diamond, it does not require to be polished.

In operation, the neck of the ampoule rests in the crook of the cutter, and with slight pressure of the thumb the diamond is brought in contact with the glass. By rotating the ampoule between the forefinger and thumb of the other hand, while maintaining a steady pressure of the diamond against the glass, an annular scratch is made, and the neck of the ampoule can be broken off cleanly and without effort.

The cutter is inexpensive, compact, light, easy to operate, and rustless, and will accommodate all sizes of ampoules. It should be a useful addition to the equipment of the medical profession.

Reviews of Books

Prostatectomy A Method and its Management

CHARLES WELLS, professor of surgery, University of Liverpool Edinburgh E & S Livingstone 1952 Pp 103 24s

THIS monograph clearly describes the Wilson Hey operation, its indications, complications, and results As Professor Wells maintains, any competent general surgeon could follow the well-illustrated description readily, whether he had seen the method or not, and could do the operation successfully

The management of the cases, with particular reference to fluid and electrolyte balance, is well described, and there is a short but interesting chapter on the history of the operation The chapter on pathology, however, is somewhat superficial, and the chapter dealing with results is not fully satisfying Professor Wells separates his personal cases from those of his colleagues, which suggests that he has, after all, some doubts whether the operation can be done by any competent general surgeon Some inconsistencies mar the generally good impression Thus he holds to Wilson Hey's retrograde catheterisation, as being necessary to maintain asepsis, but he arranges the towels so as to permit the insertion of a finger into the rectum during the operation Many urologists will disagree with the omission of preoperative cystoscopy, and many more will doubt the wisdom of giving a frail old man 10–11 pints of intravenous fluid in the first 24 hours after prostatectomy

The main teaching is sound, reflecting the modern belief in immediate prostatectomy for acute and chronic retention of urine

Professional People

ROY LEWIS and ANGUS MAUDE, M P London Phoenix House 1952 Pp 284 18s

NOBODY with any responsibility for guiding the affairs of his profession can afford to neglect this masterly account of the present situation of professions in general and the dangers facing them The authors believe that professional people have inherited the leadership in Britain today, but their "tradition of self-examining integrity and self-forgetful service" is in peril Professionalism is all the fashion, and professional status is claimed by technicians, tradesmen, brokers, social workers, administrators, and hairdressers, but these callings are not really based either on instruction in a body of fundamental knowledge or (more important) on a fundamental moral code Indeed "any claim which engineers, scientists, and technologists may have to be regarded as professional from the ethical point of view, derives very largely from their being 'the same sort of people' as doctors, lawyers, teachers, and parsons" Yet the professional tradition is badly needed "to mould, and to civilize, the specialists of the future" Believing that "the basis of professional morality lies in the fiduciary capacity of the man practising his profession," Lewis and Maude conclude that "the standards of any modern profession are ultimately maintained by the example set by private practice," and they implore doctors to retain a proportion of fee-earning practice, both for this reason and to keep in repair for N H S practitioners 'a last citadel of freedom to which all can at need, turn for safety and self-respect" They do not think that the N H S has yet shown clear signs of the insidious dangers which were freely forecast, and they congratulate all concerned, but in endorsing a statement that doctors must "remain the servants of their patients, and personally responsible for their work" they point out that the problem is to translate this into practice One possible means to this end, which they also endorse, is that doctors (like lawyers under the Legal Aid Scheme) should be paid not directly by the State but through a professional body

An independent medical profession, in Lewis and Maude's view, is second in importance only to an independent judiciary and for all their gloom, they recognise that learned institutions, frail as they may appear can simply by their professional standing, develop a strong protective front against State power

and nationally, can be useful In short, members of the true professions

"need to work much harder to strengthen an influence that is already waning, they need to protect themselves and defend their ideals, they need to face the fact that they are an aristocracy, of a sort, and to understand and uphold the personal attainments, as well as the exercise of power, which is implied in that word They certainly need the humility which self knowledge demands, and should discard the dangerous false modesty of pretending to be 'ordinary people—only an expert in this or that'"

Lewis and Maude have much more to say about medicine, and quotations from their opinions have appeared in our leading articles of Dec 20 and again this week They write with an agreeable touch of wickedness, and many will have reason to be grateful both for their perspicacity and for the expository skill already shown in their *English Middle Classes*

A Marriage Manual

HANNAH M STONE, M D, late medical director, Margaret Sanger research bureau and marriage consultation centre at the Community Church, New York, ABRAHAM STONE, M D London Gollancz 1952 Pp 314 12s 6d

THE early editions of this book established it as an outstanding piece of hygiene teaching In its revised and rewritten form it is among the best works on marriage guidance now available The good sense and humanity of its approach are much to be commended The revisions are radical, and include material derived from very recent research The rather unusual question-and-answer presentation, simulating or reproducing a personal interview, has been preserved In the hands of these authors it is highly successful, and makes the book a valuable model for the inexperienced marriage-counsellor It warns him of the type of question to expect (all the recurring decimals of sexual and psychological superstition are here) and provides accurate replies For the patient it is intelligible, reassuring, and explicit The treatment is factual, issues of conduct are dealt with at an adult level, and the style is dignified without being ponderous The book should be read by every medical student

Connective Tissues

Transactions of the Third Conference, February 14–15 1952, New York Editor CHARLES RAGAN, department of medicine, College of Physicians and Surgeons, Columbia University, New York New York Josiah Macy, Jr, Foundation 1952 Pp 166 $3 50

THE report on the first conference on connective tissues was marred by the inconsequentiality which besets impromptu discussion The speakers at the third conference adroitly avoided this, and have produced stimulating debates Perhaps the section most interesting to the general reader is that on hypersensitivity and the hyperadrenal state, which underlines the variability of antibody response among individuals within a species, and discusses much experimental work on the effect of cortisone on antibody production A section on the structure of connective tissue contains some fine electron micrographs of collagen Staining of connective tissue, and the differences between collagen and reticulin, are the subjects of the remaining sections, which give expression to a number of opinions without perhaps adding much to the sum of knowledge on these vexed topics Two coloured plates of an "allochrome" staining method for collagen and reticulin are good, but suffer from a transposition of captions

---

Signs and Symptoms (2nd ed London Staples Press 1952 Pp 783 70s)—Prof C M MacBryde, the editor of this book, offers an approach to diagnosis comparable to that of the physician at the bedside In each chapter an important sign or symptom is described, and the mechanism of its production is discussed from the anatomical, physiological and pathological angles This second edition includes some new chapters on pigmentation of the skin, bleeding and vertigo The text is well and fully illustrated This work usefully bridges the gap between standard textbooks and

More Doctors or More Ancillaries?

The behaviour of our generation sometimes recalls that of Stephen Leacock's young man whose distress of mind led him to jump on his horse and gallop off madly in all directions. Traditionally the New Year is a time for reflection—a time for drawing rein so as at least to see what road we are taking. If we knew where we were going we might well prefer to go somewhere else; and we might even be able to direct the horse accordingly. On such hopeful assumptions let us begin the year by considering some present tendencies in our society and profession.

The past quarter of a century has seen a much intensified drive towards social and economic equality. Last week Sir Geoffrey Vickers[1] described how the siege economy of Britain during and since the war has obliged us to share the essentials of existence, and how we have found ourselves paradoxically promoting more and more personal security at a time when its basis in national security grows more and more shaky. The explanation is that during the war we became a far more closely knit community, in which it seemed wrong as well as dangerous that any other member should be allowed to fall below the level of decent subsistence or that his children should lack opportunity to prove their abilities. We also came to believe—and most of us still believe—that good education for everyone, good medical services for everyone, good houses for everyone, good working conditions for everyone, and a degree of security for everyone are all, in the long run, paying propositions, and that a modern industrial nation simply cannot afford ignorance, disease, squalor, and poverty when these can be largely or even entirely prevented by applying modern knowledge. Accordingly, as a nation, we set in motion some major schemes of improvement; and these are now having some interesting incidental consequences. The modern knowledge that has needed application is possessed only by the professional or technical expert; and, in many different ways, direct and indirect, the State has had to pay professional people to perform services that individual members of the public could not possibly afford to buy. As Lewis and Maude point out in the book we review on p. 28, our Governments' programmes since the war have been creating so much new work for the professions, and for experts generally, that everywhere there is a shortage of people trained to do it. The State has in effect been subsidising the professions, which without such subsidy would probably have declined in livelihood and numbers, because the true cost of their services is rapidly becoming too high for even their former clients to meet.

To be in great demand is in some ways an agreeable situation. Bureaucracy may, as Lewis and Maude say, be "a voracious user and spoiler of professional talent," and it will always threaten the professional freedom and responsibility that are essential for really good work; but the medical care of the people of this country is certainly far better at present than it would have been without large Government expenditure on its provision. The danger, as Lewis and Maude see it, lies in a later lowering of standards when the State finds that it has undertaken to do more than it can pay for. Having accepted the principle that, so far as education or medicine is concerned, every citizen has equal rights, the State must try to provide the best for everybody—which is as inconvenient in practice as it is difficult in logic.

> "If you promise to make 'the best available to all,' you cannot pick and choose among priorities. You cannot tot up the figures and say, 'we can afford the best possible treatment to eliminate the scourge of tuberculosis, and we can give a 100 per cent. dental service to children and expectant mothers—because we think these priorities will pay the best dividends on the investment—but we shall have to cut down on hearing aids and massage.' This is to admit that no attempt is to be made to make the best available to those who are neither tubercular nor pregnant, but who do happen to be deaf and suffering from fibrositis. Social justice would be outraged by such arbitrary decisions. The result, of course, is that the best is made available to no one at all."

Actually it is pretty generally understood that, outside utopia, the best of everything cannot be guaranteed for everyone, even in a national service.

> "A modicum of legally enforceable rights may be granted," says Marshall,[2] "but what matters to the citizen is the superstructure of legitimate expectations. . . . It may be possible for every citizen who wishes it to be registered with a doctor. It is much harder to ensure that his ailments will be properly cared for. And so we find that legislation, instead of being the decisive step that puts policy into effect, acquires more and more the character of a declaration of policy that it is hoped to put into effect some day."

Most of us recognise this. Nevertheless, as Marshall adds, in a progressive society the expectations of the public are bound to rise: "the target is perpetually moving forward, and the State may never be able to get quite within range of it." And it is here that Lewis and Maude foresee trouble for the professions which work the social services. When funds prove insufficient to supply all that the public has been led to expect, the State may let the quality of its benefits go down in order that it may still provide them in the promised quantity. This, in their view, has already been happening in the teaching profession, as a result both of the increase in the number of school-children and of "the rash promises" of better education for all. The general average over the whole educational terrain may not have fallen very greatly; but many young men and women are qualifying as teachers who would not have been acceptable before the war, the decline in standards of grammar-school teachers (with its serious implications for the next generation) has become notorious, and unqualified persons are being sought to assist in the control and instruction of over-large classes.

The preservation and improvement of medical standards in the interest of the public is one of our primary duties, and the fact that, mainly for economic reasons, our care of patients is now organised and financed by the State must not be allowed to lead to deterioration of these standards. Lewis and Maude draw attention to one way in which such deterioration might take place when they point out that, in the name of economy, a Government might refuse to adjust the remuneration of doctors to changes in the cost of living and in what can be earned in other occupations. Here we have the unhappy precedent of the recent and continuing deterioration of the medical Civil Service through failure to revise its salary scales; and if the same thing happened in the National Health Service we should eventually see doctors, like teachers, recruited from young men and women of inferior ability and attainments. This financial danger, however, can hardly be regarded as immediate; and we may also dismiss for the moment the possibility that the State will be foolish enough to cease its comparative generosity to the grammar schools of medicine—the teaching hospitals. If a warning parallel is to be drawn between the educational and medical professions, it is the employment of unqualified persons as ancillary school-teachers that seems most nearly comparable to developments in medicine. Indeed the proper use of ancillaries is a major issue on which doctors ought to be clearing their minds and forming a considered opinion.

---

[1] *Lancet*, 1952, ii. 1265.

[2] Marshall, T. H. Citizenship and Social Class. London, 1950; p. 58.

It is easy to see that rapid expansion of a profession in response to State subsidy endangers both its quality and status: if the need to expand becomes an excuse for recruiting the second-rate, a vicious spiral is soon in operation. Hence for our own part we should endorse LEWIS and MAUDE's warning against this form of professional dilution or inflation; and it may be remembered that more than a year ago we suggested that the intake of medical students was already too high and should be re-examined.[3] The fact remains, however, that there is a vast amount of work to be done by somebody; and we do not share these authors' apparent objection to the other form of "dilution" which consists in employing people with lower qualifications to do a large proportion of it. Whereas they disapprove of the proposal to allow dental ancillaries to fill and scale children's teeth under the supervision of a dental surgeon, to us this seems a rational and economical way of meeting an admitted need while safeguarding the professional position of the qualified dentist.[4] If there are not enough dentists, or doctors, to do what is required of them, the choice before each profession is between (a) delegating some of its work to ancillaries and (b) enlarging its own membership. If, in choosing enlargement, it makes the mistake of opening its doors too wide, the result will inevitably be a lowering of standards and status; but no such harm need follow judicious delegation of work, which on the contrary can be a means whereby standards and status are maintained and enhanced. Actually, of course, doctors have long made steadily increasing use of ancillaries of every kind, from nurses to chiropodists, from speech therapists to psychiatric social workers; and there are those who feel that, whatever the advantages may have been in the past, the claims of some of these groups of technicians to be members of sister (rather than daughter) professions[5] have now begun to weaken the position of the qualified medical practitioner. SIR HENEAGE OGILVIE, for example, looks on the tendency with foreboding:

> "It is easy," he says, "to see how a ruthless Minister of Health, determined to reduce the cost of the service and to break the cartel of doctors, could set about to dilute labour. An optician would see all cases referred to ophthalmic outpatients, keeping only the unusual ones for the ophthalmologist. A nurse, given a course in the use of specula, could, with the help of a welfare worker, deal with two-thirds of the otolaryngological outpatients. A chiropodist with a box of Scholl's supports would lighten the work of the orthopædic surgeon at outpatients, and a plaster technician would do the same for him in the theatre. In general surgery the meticulous but tedious work of opening and closing wounds could be handed over to an unqualified assistant, allowing the surgeon to do twice as many operations in a session."[6]

Nor is this picture as fanciful as it may sound. We shall shortly be publishing an analysis of the activities of child-welfare clinics from which it is deduced that "the advisory work of the clinic medical officer might now be taken over by the health visitor"; we hear murmurs that much more of the work of radiologists could be just as well done by radiographers; and we see practitioners at experimental health centres provided with clerks to do their paper work and nurses to do their dressings and injections. Is this kind of dilution of medical labour really an insidious peril to the sound practice of medicine? Or is it merely a victory for common sense? Before it goes much further we shall all have to decide whether we approve or deplore it, whether we should welcome or resist it.

With so many different kinds of technician taking part in medicine "the distinction between work which requires and work which does not require a medical qualification is blurred," as FFRANGCON ROBERTS has remarked.[7] Yet it is still perfectly clear that the care of patients, with ultimate responsibility for them, is the function of a medical doctor, who alone is qualified to undertake it. Whatever help we may accept from ancillaries, the task falling on our profession is and must remain immense. There are some 50 million people in this island, all of whom should be equal in our eyes and every one of whom is entitled to expect, whenever he needs it, the attention and care not of an orderly or a laboratory assistant or a photographer but of a fully capable medical practitioner—that is to say a man or woman with courage, energy, understanding, and the wide knowledge required to enable his patients to gain rather than lose by advances in technique. A little knowledge is no less dangerous because its possessor deprecatingly describes himself as a G.P.; and one thing we must certainly resist is the tendency, by depriving him of clinical responsibility, to create an ignorant kind of practitioner who while retaining the title of doctor and the nominal charge of patients is really little more than a contact man prepared to make arrangements with hospitals and specialists. The interests of the public will be ill served by any change that prevents our profession from securing the ablest and most devoted of the young men and women who feel that they have a vocation either for practice or for the more technical side of medicine; and they will be equally ill served by our accepting entrants who are neither able nor devoted. But if in fact we reach the conclusion that the only practicable means of preserving good standards and conditions of work is a closer restriction of our intake of students, surely we must then accept the obvious alternative to more doctors—namely, more ancillaries. The further dilution of medical labour by ancillaries need not be damaging provided everyone acknowledges that the person who is in clinical charge of the patient at any given time, be he consultant or practitioner, is the leader of the team working for that patient—even if all the other members of the team are fellows of the Royal Society. And this position of leadership could scarcely be challenged except for one reason—that the doctor's calibre had been allowed to fall below what is necessary for discharging his supreme responsibility.

Thus, as happens so often in New Year reflections, we are brought back to ourselves. Though it may be more congenial to try to stop a technological tide from rising, or to put back a social clock, it is probably better in the end to concentrate on keeping, or setting, one's own house in order. The moralists—always so busy at this season—remind us that in the long run a man's status and influence depend on what he is and does; and if our profession proves itself able and willing to give people all the help they ought to get from doctors, it need have no fear of social tendencies or any other threat to its future.

Atelectasis Neonatorum

Prematurity accounts for a large proportion of neonatal deaths, and commonly the cause of death is failure of the respiration for one reason or another. The death of such infants is likely to cause particular distress to the parents, since it seems that prematurity is especially common among older women and those who have already had an abortion or stillbirth. The full-term infant, also, may fail to breathe after birth.

At birth the lungs of the mature infant are structurally not unlike those of an older person, in that the lung alveoli are lined by thin flattened epithelium and have a rich supply of capillaries; there is a considerable amount of elastic, and not much connective, tissue. In other words, the lungs are sufficiently developed to permit the easy exchange of gases as soon as respiration begins. The mature baby also has active reflexes, a responsive respiratory centre, and fairly strong thoracic muscles. Potter [1] believes that immaturity of the respiratory centre is probably never responsible for failure to breathe after birth; but the premature baby has a number of disadvantages whose degree depends on its age since conception. Firstly, the lungs are not only small in relation to its size, but poorly developed; many of the alveoli are lined by cubical epithelium, which forms a relatively solid barrier between any entering air and the inadequate number of capillaries in the alveolar walls. Secondly, the respiratory muscles are weak, and the infant may become exhausted by the efforts demanded of it. In both mature and premature babies respiratory failure often follows atelectasis. On an earlier page of this issue Dr. Donald and Dr. Lord discuss some of the factors responsible for this state of affairs, and describe methods they are pursuing to help the infant struggling for breath. Often asphyxia causes atelectasis, which may, in turn, lead to further asphyxia. Intra-uterine anoxia can initiate respiratory efforts by the fœtus which result in the inhalation of liquor amnii. This is probably not serious to the healthy full-term infant; and, in fact, it may be a normal, though not a regular, feature. In both man and animals movements of a respiratory type have been observed in utero [2]; and 'Thorotrast' injected into the amniotic sac has been identified some hours later deep in the lungs of the fœtus.[3] There is some evidence that these respiratory movements are more readily initiated in the early than in the late fœtus.[4] The healthy mature baby seems to absorb rapidly any amniotic fluid it may have inhaled. Both premature and anoxic infants, however, deal less effectively with such fluid. Anoxia may cause venous and capillary congestion which, particularly in the premature baby, readily leads to hæmorrhages and œdema; these, in turn, disorganise the responses of the central nervous system and prevent absorption of fluid from the lungs. In fact, the œdema will add to the fluid present in the alveoli and render the lungs still more rigid and inexpansible. Anoxia, œdema, and atelectasis form a vicious circle. Secondary atelectasis is more rare than the primary form. Leaving aside cerebral damage and congenital defects, it may follow the formation of hyaline membrane or pre-existing pneumonia. Owing to its elasticity the infant lung contains little residual air; and this may be reabsorbed just before death, giving rise to the appearance of atelectasis.

The obvious requirements for preventing unnecessary deaths due to atelectasis are the avoidance of prenatal or neonatal anoxia—or, failing this, rapid treatment. The simplest treatment is to keep the airways clear and provide oxygen and good nursing. For many infants this is enough; but others need more active help, and for this group Donald and Lord have devised a respirator. The first need, as always in rational treatment, is to determine normal requirements. Neonatal respiration has been investigated for many years, but it cannot be said that our information is yet satisfactory or complete. Donald and Lord describe a spirometer used to measure respiration in normal and premature infants. This is, in essence, a Krogh spirometer into which expired air passes through a simple non-return flap valve. When it is filled to a known extent an electrical device empties the float chamber, which returns to its resting position, and the filling process begins again. The movements of the float are recorded and calibrated. A rubber oxygen mask of United States army pattern, applied upside down, was found to fit the infant face satisfactorily. This apparatus is useful, not only for preliminary determination of normal behaviour, but also for assessing whether a baby needs assisted respiration, and for clarifying diagnosis—for example, to determine whether the respiratory difficulty is due to atelectasis or to the onset of pneumonia. These workers prefer a mask to a plethysmograph [5] since it involves less disturbance of an ill baby in its incubator; and the apparatus can be made cheaply and quickly. Additional information was obtained by means of radiography. The normal values were somewhat higher than those recorded by Cross,[5] whose figures are probably the most accurate yet obtained; for clinical reasons, Donald and Lord could not insist on absolute resting values. Regarding lung expansion, they observed full expansion within 30 minutes of birth. The respirator has been designed for cases in which atelectasis persists or develops secondarily. A Drinker-type apparatus did not prove wholly satisfactory for this purpose, owing to its relative functional inflexibility. Even in healthy premature babies respiration may be very irregular,[4,6] so that one of the dangers of artificial respiration is hyperventilation with consequent alkalosis. Furthermore, newborn infants vary widely in their rate of respiration.[4,5] These difficulties have been avoided by developing a machine that amplifies spontaneous respiratory efforts only. A photo-electric mechanism actuated by a light mirror attached to the flap of the inspiratory valves, is sensitive to the first 0·1–0·2 ml. of attempted respiration; it is effective with breaths too feeble to be measured by spirometer. Either negative or positive pressure, or both, can be applied to the body. With respirators of the plethysmographic type it has proved difficult to find an efficient method of sealing the neck or face from the body-chamber. Neck seals hitherto tried may cause "pistoning" of the whole child or, particularly if it cries or struggles, engorgement of the blood-vessels of the head and neck. Donald and Lord use a rapid-setting alginate which can be injected around the neck, or around the entire head and neck leaving only the face free. The mask is embedded in the alginate. They prefer to leave only the face free as "pistoning" is thus avoided, and should spirometry be needed readings are more likely to be accurate. The alginate can be easily broken and removed by the fingers. This method might be thought to restrict the sick and restless infant, but it appears to give satisfactory results. The alginate remains competent at pressures rather lower than −15–30 cm. water. With regard to safe pressures, Donald and Lord have seen no harm follow the use of −40 cm. water, and once they used −65 cm. with no evidence of pulmonary damage. This agrees with the finding of Smith and Chisholm[7] that mature, and even some premature, babies could exert negative pressures of 40–50 cm. water. It would seem undesirable to use pressure of this degree for more than a short time, and Donald and Lord have found that −15–30 cm. water is sufficient.

These workers follow the usual routine after the infant's birth, and they consider using the respirator only if atelectasis persists. Endotracheal intubation is avoided, especially in premature infants, and gastric oxygen is given instead if the baby needs assistance before it can be put in the respirator. Fortunately the newborn, and especially the premature, infant, seems to withstand pronounced oxygen lack; moreover, the tissues are thin so that a fair amount of oxygen passes into the blood from the stomach, and the hæmoglobin has a greater affinity for oxygen than that of the older baby or adult. This respirator overcomes the serious disability of weak musculature. In the feeble anoxic infant struggling for breath the diaphragm exerts a powerful downwards pull. If the cohering or blocked alveoli do not expand, the intrathoracic subatmospheric pressure is transmitted to the chest wall. This force may be considerable.[8] The soft ribs and weak intercostal muscles are sucked in, with resulting sternal retraction. This makes matters worse, since the pressure on the lungs still further obstructs the entry of air. When negative pressure is applied outside the chest, as in the respirator, sternal retraction is prevented and the subatmospheric intrathoracic pressure is applied where it is most needed—namely, to the lungs. Donald and Lord give a mixture of 50% oxygen and 50% nitrogen. The anoxic infant needs oxygen but not carbon dioxide, which is probably already at a high concentration in its blood. On the other hand, too high a concentration of oxygen is toxic and damages the pulmonary epithelium. Cross and Warner[9] found in infants, as did Dripps and Comroe[10] in adults, that 50–60% oxygen after a short initial depression of respiration stimulated ventilation. One obstacle to assured success is the formation of hyaline membrane. Little is known of the causes of this condition, which may supervene after a period of apparently normal breathing. At necropsy the appearance sometimes suggests that resorption of fluid has caused the deposition of granular material in an increasingly thick layer, which has blocked the alveolar ducts and obstructed the alveoli.[1] Potter[1] has the impression that the incidence of hyaline membrane has been reduced in the Chicago Lying-in Hospital since infants with signs of respiratory distress have been given oxygen in which the humidity is maintained at 90–95%.

Dr. Donald and Dr. Lord describe their account of the new respirator as an interim one; but already they can claim three cases, and perhaps a fourth, as successful results as far as saving life is concerned. They are, with some success, doing their best to treat results; but we greatly need more information about causes, so that fewer newborn infants will have to struggle against anoxia.

Carcinogenic Aromatic Amines

We have lately commented[11] on the research which is being undertaken into the subject of bladder papilloma and carcinoma as an industrial hazard in the chemical industry. Although this danger has been recognised for nearly sixty years, and much has been done to reduce the contact of the workers with noxious chemicals, the progress towards an explanation of the fundamental causes has been slow. The dog was the only species known to be susceptible to these tumours, so that an individual experiment required up to ten years for its completion; for a long time attempts to find a reason for the unusual localisation of the tumours in the bladder epithelium, while all other organs remained apparently normal, failed. It was, therefore, an important step when Bonser, Clayson, and Jull[12] found that the urine of dogs treated with β-naphthylamine contained a carcinogenic metabolite derived from this substance. This metabolite was a water-soluble orthohydroxyamine, 2-amino 1-naphthol, and its tumour-inducing properties were demonstrated by a new technique of implanting a pellet of the chemical suspended in wax into the mouse bladder.[13] A series of experiments has now confirmed that the metabolite is carcinogenic, whereas the parent amine

not.[14] Moreover, an insight was gained into the metabolism of this substance in different species [12] —another important landmark in the chemical investigation of the disease. β-Naphthylamine is only one of a group of some twenty aromatic amines which have been tested for carcinogenic activity in recent years. Although there is no uniformity in the location of the tumours or in species susceptibility, these chemicals all tend to induce distant carcinomas at sites along the routes of excretion. The addition of new carcinogenic members to this group and the collection of more information about their mode of action may lead to the discovery of a common metabolic plan for a diverse, though related, series of compounds, some of which are used in industry.

Scott [15] has produced good evidence to show that the manufacture and handling of benzidine, another aromatic amine, involve a risk of carcinoma to the workmen. His extensive investigation confirms the findings of Billiard-Duchesne [16] and Désoille et al.,[17] and seems to put the carcinogenic action of benzidine beyond doubt. On the experimental side, Spitz et al.[18] had already shown that this chemical induced hepatic, intestinal, and acoustic-gland tumours in rats and (more doubtfully) bladder tumours in dogs. A chemical closely related in structure to benzidine is 4-aminodiphenyl, which has been shown by Walpole et al.[19] to be carcinogenic in the rat. It seems possible that this compound may have been present in distillation residues from aniline in dye factories, though it is probably not so today. In this experiment the commonest tumour was in the large bowel; of 14 rats which survived five hundred days, 7 had epithelial tumours of the large bowel, the exact nature of the growth being uncertain. It may be accepted, however, that the tumours varied in their degree of "progression," [20] and that the most advanced of them had probably reached early malignancy. Methylation is a well-known method of increasing carcinogenicity, and when methyl groups were substituted in both the benzene rings of 4-aminodiphenyl, giving 3 : 2′-dimethyl-4-aminodiphenyl, its carcinogenic power was much greater. Intestinal tumours were commoner and they developed earlier in both large and small intestines. Miller et al.[21] also found that another methylated diphenyl (N : N-dimethyl-4-aminodiphenyl) induced tumours in various organs (but not in the bowel) earlier and more often than 4-aminodiphenyl did in the later experiments of Walpole and his colleagues. The latter concluded that the effective carcinogen in all these cases was a metabolite of the particular amine being tested, and that in the rat these metabolites were excreted in the bile. They suggested that, by analogy with the work of Bonser et al.[12] and others, the effective metabolite is an orthohydroxyamine, and that when *o*-methyl or N : N-dimethyl substitution takes place, metabolic hydroxylation is "steered" into the ortho position relative to the amino group, and carcinogenicity is increased; but these interesting suggestions as yet lack experimental proof.

An American group,[22] led by the Millers, have investigated some aromatic amines and azo compounds in another way. They have done much work on fluorine substitution in various positions in the benzene-ring systems of these compounds. The effect of this substitution is to form a tight bond so that particular positions can be blocked, as it were, against metabolic activity. They concluded that the amino-azo dyes are carcinogenic to the extent that they are methylated in vivo and bound to the liver protein.

The metabolism of the aromatic amines in the widest sense lends itself well to organic chemical analysis; and it would be valuable at this exciting stage of the inquiry into their carcinogenic properties to try to forecast which compounds should most profitably be tested. Each amine requires months of careful study in at least two species (the dog and the rat or rabbit) before the final investigation of the carcinogenic power of its metabolites can be made. Nevertheless, remarkable progress has been made in a few years, and it is reasonable to hope that the problem will be solved before long. The knowledge thus gained may point the way to fruitful investigation of the metabolism of other types of compound. Doctors who see many patients with malignant disease every day are sometimes irritated by the reports of work on this carcinogen or that —work which seems to them to be far away from human disease. But research of this kind is essential to an understanding of the way in which the body is likely to react to carcinogens, and it therefore has an important place in the complete picture of malignant disease.

Annotations

"DISABILITIES"

Our series of articles, written by people disabled by disease or injury, have been widely read; and we may say—without taking credit to ourselves—no wonder. These writers, setting out to show how they have got the better of their handicaps, in great ways or small, unconsciously display so much courage, cunning, and humour that the collected pieces are a testimony to the human spirit. They have now appeared as a book,[23] which should, we think, appeal to laymen as well as doctors.

A CHALLENGE MET

Last summer Denmark was struck by an epidemic of poliomyelitis which was far more severe than any previous one in that country. Professor Lassen, whose account of his experience in Copenhagen during the past six months appears on a later page, is probably right in supposing that "nothing comparable has ever been seen in Europe." Between July 24 and Dec. 3, 866 cases with paralysis were admitted to Blegdam Hospital, Copenhagen; and 316 of these required special measures—such as tracheotomy, artificial respiration, postural drainage, or a combination of these. In four months the hospital dealt with three times as many cases with respiratory insufficiency, paralysis of the ninth, tenth, and twelfth cranial nerves, and involvement of the bulbar respiratory and vasomotor centres as in the preceding ten years

[23] Disabilities. London: The Lancet Ltd. 1952. Pp. 243. 10*s*. 6*d*. (postage 6*d*.).

With rare exceptions death in the acute phase of poliomyelitis is due to respiratory failure or embarrassment, either from involvement of the anterior-horn cells leading to impaired *movement of the diaphragm* and intercostal muscles or from damage to the bulbar area Since the introduction of Drinker's tank-type respirator in 1928, much attention has been given to developing similar but smaller machines, such as the cuirass type Intelligently used, these machines have tided over a crisis many patients who would otherwise have succumbed, less happily, they have created a tragic problem in the invalid who depends permanently on the respirator Respirators, however, will rarely help —and indeed are more likely to harm—patients with respiratory insufficiency from lesions of the lower group of cranial nerves The fatalistic attitude towards severe respiratory paralysis has been countered by the strong advocacy of tracheotomy by American workers, notably Bower [1] and Galloway [2] In Britain this method has only *occasionally* been *practised, though* Kelleher,[3] impressed by the American claims, made a plea for team-work to further its use On this side of the Atlantic, however, it has been left to Professor Lassen and his fellow-workers to apply on a large scale this method in conjunction with others

His figures show that the method has helped to reduce by more than half the mortality from bulbo spinal respiratory paralysis This improvement has been achieved largely by combining tracheotomy with positive-pressure respiration by manual compression of a rubber bag The use of such a device as an accessory to tank-type respirators is commonplace, but complete dependence on it is something new, originating perhaps in Denmark's shortage of mechanical respirators which, despite the ready help of neighbouring countries, have been far too few for all the cases By the Copenhagen scheme a closely fitting inflatable cuff tracheal tube is applied through a tracheotomy, and artificial respiration is maintained indefinitely (in some cases for more than three months) by manual rhythmical compression of the bag, at a rate of 16 to 30 per minute Additional measures—and notably tracheal suction—are applied as need arises 250 tracheotomies have been done in the 316 cases requiring special measures The results varied with the sex and age of the patients, being worst in men (56% mortality) and best in *children It is notable* that of 10 patients with spinal-type respiratory paralysis who were treated exclusively in tank-type respirators, all but 1 survived, which emphasises the value of such apparatus in selected cases Among 11 children treated by respirator and tracheotomy 45% died compared with 38% in a group of 74 children treated by tracheotomy and positive pressure (bag) ventilation

If, as seems possible, this technique marks an advance in the treatment of bulbo-spinal poliomyelitis, it represents a triumph for *enterprise* in the face of an overwhelming outbreak On the human side our Danish colleagues should be congratulated on mustering the large amount of skilled help that the new technique requires To compress a rubber bag at a constant rhythm will tire the most enthusiastic after an hour or two and the operator has also to keep a watchful eye for the restlessness or irritability that is the first token of oxygen lack, and which usually calls for tracheal suction Any who have visited Blegdam Hospital will attest *to the patience* and efficiency with which students are doing this work—and to the remarkable contentment of the patients

A SURGICAL INQUISITION

WOULD the standard of surgery in a particular hosp be raised if a *more searching assessment of the re* was made by independent observers? An experime has been carried out in the United States to see wheth it would [1] In a certain hospital a committee of 7, com posed of 5 general surgeons, an orthopædic surgeon, an a pathologist, held a monthly meeting to scrutin the results of the operations performed and to jud *their value In every large hospital* an unknown sma proportion of operations are performed which are lat proved to be unnecessary Perhaps the preoperativ clinical examination could have been more detailed perhaps the surgeon could have sought a second opinio with advantage, or perhaps further investigations coul have been profitably performed The object of th American committee was to correct these errors b analysing case histories in the light of the pathologic reports and the patient's ultimate condition

To begin with, the committee considered cases wh fell into one of six categories (1) operations involvin the reproductive organs, (2) appendicectomies, (3 operations after which the pathologist reported little o no pathological change in the organ removed, (4 operations which were followed by an abrupt change i the diagnosis, (5) emergency operations, and (6) al operations in which no tissue was removed—e g, uterin suspensions The committee were hard at it, for over month 100 cases came before *them, so each member too* on one of the categories If he had any criticism t make, the whole committee then discussed the particula case Not unexpectedly, each meeting lasted for fou hours or so It was not only the operating surgeons wh had to face this criticism, for the advice of the con sultants was also examined When the work of th *committee got going,* the *number of normal appendic* removed was greatly reduced in a few months Fo example, the records showed a considerable differenc between two surgeons Mr X took out few norma organs whereas Mr Y removed many, a word to Mr Y and his "normal" figures fell The committee though *that too many suspensions* of the uterus were bein performed, so rules were drawn up setting out th conditions that justified this operation A considerabl fall in the number of suspensions followed The wor of the committee is also said to have encouraged mor careful note taking and prompted a search for mor confirmatory evidence before deciding to operate

But there are better *ways of encouraging good work* Probably the best is to train the apprentice surgeon s well that he would never think of operating before h had sought all possible evidence The selection of me for senior surgical appointments is difficult enough o professional qualifications alone, but it should als include an estimate of the candidate's pertinacity i seeking such evidence and his thoroughness in weighing it, for the successful applicant must share the task o training the younger men Moreover, can we be certain that a committee *will judge correctly? Personal* considerations are certainly eliminated by identifying the case-reports by number only, but may not th committee, by laying down rules actually hinder progress or prevent the best being done for the patient? Must we accept the rigid belief that appendicectomy is only justified when pathological changes can be demon strated in the removed organ? Is it not possible that catarrhal appendicitis may resolve completely and th organ return to normal, as the pharyngeal tonsil does? Yet the patient may soon have another attack in whic the appendix may become obstructed and dangerous— not because it is altered structurally but because the immunity of its lymphoid tissue to bacterial attack is paired. If the history, symptoms, and signs strongly ggest an attack of acute appendicitis that has subded, then there are good grounds for removing the ppendix before it can do serious harm—and the decision ould be justified whether it showed pathological changes r not. It certainly seems preferable to concentrate on ethods of training the surgeon rather than to set up a ommittee to censure him after he has been appointed o a responsible position.

ALZHEIMER'S AND PICK'S DISEASE

It is easy to understand that gene mutations should cause mental defect or childhood dementia. It is perhaps more remarkable that they should also determine diseases with onset in late middle life. Yet Huntington's chorea, one of the three main types of presenile cerebral degeneration not caused by vascular disease, has long been known to be due to a dominant mutation. This condition is relatively uncommon; but the two other types, Pick's disease and Alzheimer's disease, together account for about one-tenth of all senile and presenile dementia. Individual pedigrees have suggested that Pick's disease and, less certainly, Alzheimer's disease are partly due to genetic factors, though these pedigrees do not show any simple mendelian pattern.

Sjögren and his colleagues [1] in Sweden have made a determined attempt to find out more about these two conditions. Their index cases were 18 patients with Pick's and 18 with Alzheimer's disease. In each of these the diagnosis had been confirmed by necropsy. The cases of Pick's disease showed the characteristic massive but circumscribed atrophy of the frontal and temporal lobes with ballooning of residual neurones and much reactive gliosis; the basal ganglia were rarely affected. The cases of Alzheimer's disease had a less intense but wider atrophy of the cerebral cortex with fibrillar degeneration of the remaining neurones and numerous senile plaques; changes in the basal ganglia were common. In some of these cases the affection was senile rather than presenile, but the average age of onset in each group was close to the 54th year. Clinically the patients with Pick's disease first developed amnesia and then progressive dementia. Those with Alzheimer's disease showed striking disorientation in space, even losing their way about their own homes. A characteristic finding in the patients with Alzheimer's disease was that nearly all showed an increase in muscle tone and an unsteady gait, but not the tremor and pulsion disturbances seen in parkinsonism. Sjögren and his associates regard this abnormality of tone as the best point on which to differentiate clinically the two types of dementia. Their patients with Alzheimer's disease, unlike many others reported, did not show hyperactivity, and most were predominantly apathetic.

In the family study of the two groups of 18 patients it was found impossible to distinguish between senile and presenile dementias among relations, since no necropsy reports were available. In each group 3 of the 36 parents had senile or presenile dementia, and in each group 1 sibling had such a dementia. The incidence of presenile and senile dementia together is estimated to be about 1% in Sweden, and so it seems probable that the frequency of dementias of this kind is increased in the near relations of patients with Pick's and Alzheimer's disease. Family studies of 44 patients in whom either Pick's or Alzheimer's disease was diagnosed clinically agreed closely with those based on the histologically proved index cases; and in the whole sample the risk of parents being affected was 10 ±4% for Alzheimer's disease and 19 ±5% for Pick's disease; the risks for brothers and sisters was 3·8 ±2·1% and 6·8 ±2·9%.

Professor Sjögren tentatively suggests that Pick's disease may be due to a dominant gene of incomplete penetrance, and that Alzheimer's disease is determined by multifactorial inheritance. The next step would seem to be to make post-mortem histological studies of the relations with dementia. One might find, for example, confirmation of Sjögren's hypothesis, in that relations of patients with Pick's disease had Pick's disease, while relations of those with Alzheimer's disease tended to have non-specific dementia with rather early onset.

A surprising feature of the investigation was that the great majority of the patients with Alzheimer's disease came from Gothenburg, while all but 3 of the patients with Pick's disease came from Stockholm.

A NEW KIND OF HOSPITAL FOR DIABETICS

Thanks to the enthusiasm of Dr. Elliott P. Joslin and his colleagues at Boston a new undertaking on behalf of diabetics is projected.[1] Though diabetic patients now live three times as long as their forerunners in the early part of the century, and though coma, tuberculosis, and gangrene are now seen in only about 1% of cases, the fact remains that after 15–20 years of diabetes few patients escape the serious complications of retinitis, neuritis, or nephropathy. Yet, as we have recently noted,[2] the team at the Joslin clinic are confident that if young and hopeful diabetics are taught properly how to manage their disease, such complications need never develop. Instruction of this detailed kind can only be given in hospital; but hospital costs are rising, in America as here. Fortunately the clinic has three funds at its disposal, administered by an advisory committee of which Dr. Joslin is chairman. One of these—the Diabetes Camp, Home and Hospital Fund—can appropriately be used, if supplemented from other sources, to build for this purpose a special hospital of which the running costs would be relatively small. The patients would not be bedfast: on the contrary they would presumably be fit and mobile, more like a class of college students than a group of sick people. Hence they would not need the ward care of nurses, but could very largely be left to their own devices. The hospital, then, could give them meals at a cafeteria, and provide them with "opportunities to do light housekeeping such as is the rule in boarding schools and colleges." Such a plan has long been advocated here, for patients who come to hospital for investigation rather than treatment, and who do not need bed rest or nursing care[3]; but it has not, as far as we know, been tried. The Boston experiment should therefore teach us a good deal.

Land for the new hospital site has been partly given, partly bought by the fund; plans are now being drawn up, and building is to begin this year. The hospital teaching clinic will be on the second floor, and the first floor will be let as consulting-rooms for doctors—an arrangement which should help to cover expenses. Lectures will be given in the adjacent Cancer Research Buildings; and research laboratories for diabetes are also near at hand. Not only diabetics but doctors, medical students, and nurses will be instructed in the prevention of the long-term complications of the disease. The existing fund is insufficient to cover the necessary outlay, but the advisory committee hope to receive enough gifts and subscriptions to meet costs as they arise, even though these are bound to be considerable. They say, simply and sincerely, "We cannot bear to see boys and girls rescued from coma live to have distressing complications later, ending in prolonged illness, suffering and death. If those who read the report saw as we the result of uncontrolled diabetes, the money for the Hospital Teaching Clinic would come soon."

INFLUENZAL WOOD AND TREES

THOSE engaged in typing influenza viruses have long envied their colleagues concerned with similar problems among bacteria Thus, *salmonellæ* have a more three-hundred-odd serological types, while the pneumococcus and the diphtheria bacillus can boast little more than sixty Compared with these figures, the number of serological subtypes of the influenza-A viruses seems to the investigator as the sands of the sea It is with real gratitude, therefore, that he will turn to a recent account, by Dr George K Hirst,[1] of an attempt to introduce greater order into the serological study of these viruses

Conventional serological methods measure at the same time qualitative and quantitative differences in antigenic composition of influenza viruses Hirst has studied a large number of strains with virus-absorbed sera which indicate qualitative differences only Among influenza virus strains isolated between 1933 and 1947 Hirst finds six main type-specific antigenic components, though there are strong hints of more to come With one exception all the strains studied showed only one type specific component, along with a group specific antigen which is common to most of the strains and confers the influenza A characters The bewildering variety in the antigenic make up of the influenza viruses is accounted for by quantitative variations in these basic components

To those who are not serologically minded it will come as a relief that when the minutiæ of the trees have been explored we get a fascinating picture of the wood The general pattern which emerges is that one type specific antigen at a time is widely distributed throughout the world for a few years until it is replaced by a new antigen, which then dominates the scene for a few more years The occurrence of a new antigen is so rare in comparison with the large numbers of serologically similar strains which have been found during one epidemic period that we have no reasonable alternative to the view that mutation of the virus has occurred on a single occasion, followed by widespread dissemination of the new antigenic subtype The dominance of the new type and the disappearance of the older types is readily explained by widespread immunity to the latter Presumably, therefore, virus bearing a new antigen which is closely related serologically to its predecessors will appear less "virulent" than one which is distantly related

Studies with virus absorbed sera have been few because of the many technical difficulties Hirst's technique illuminates much that has been done by conventional serological methods, although it is unlikely to replace them in general use Like much of Hirst's previous work, this unspectacular study gives a sure enough foundation to bear the weight of much future speculation

CORTISONE IN PREGNANCY

THE effect of cortisone in pregnancy deserves special assessment, and the subject has had relatively little attention Pregnancy is associated with retention of water and sodium, and with an increased urinary output of corticoids[2], and both these changes indicate special activity in the mother's adrenal cortex The case of the patient who becomes pregnant while under treatment with cortisone raises the question of its effects on reproduction and gestation

In rabbits De Costa and Abelman[3] found that cortisone interfered with conception, when given in 15 mg doses daily for several days before mating, but it had little effect on conception when given after mating Preg does were given cortisone daily for various per throughout gestation, and only a third of th gave birth to live young In the rabbit, there cortisone seems to lower the chances of a success pregnancy

In women the effect of cortisone on menstruation variable, but a succession of normal menstrual cyc is common enough during treatment De Costa a Abelman described 5 cases in which cortisone was giv during pregnancy In 2 of these cases (rheumato arthritis and reactivated rheumatic fever) concepti took place during a long period of treatment wit cortisone, 1 woman aborted spontaneously two month after treatment was stopped, and in the second therapeutic abortion became necessary, in both cases the fœtus and placenta were normal In the 3 other pregnancies cortisone given in mid-gestation or later seemed to have no effect on the pregnancy, and live healthy babies were delivered Doerner et al,[4] in an attempt to influence rhesus sensitisation, gave cortisone to 2 women in the later months of pregnancy Neither showed untoward reactions, but there was no appreciable change in antibodies While the published evidence is somewhat scanty, it seems that cortisone is harmless in human pregnancy, at any rate when given after the sixteenth week Possibly cortisone causes a release of œstrogens, and it is known that œstrogens cause abortion in rabbits, but not in women

In conditions complicating pregnancy the possible effect of cortisone on the pregnancy may be a consideration secondary to its effect on the complicating disease In toxæmia the rôle of the adrenal gland is obscure, and it may be argued that the salt-retaining properties of cortisone could precipitate convulsions in a pre eclamptic patient Indeed, fatal convulsions, though rare, are not unknown during cortisone therapy[5] However, the beneficial effects of cortisone on the œdema of nephritis[6] encouraged Moore and his colleagues[7] to give cortisone to 8 patients with toxæmia in whom termination of pregnancy was indicated In all 8 there was considerable clinical improvement, and 7 of the women were delivered of live babies The results in this small series are hopeful, and provide another example of the versatility of cortisone in modifying symptoms Clearly, however, this drug should at present be used warily in early pregnancy—in hyperemesis, for instance

VACANCIES

BEFORE the late war we published each week a list of the vacant appointments for which applications were invited in our advertisement columns In 1940 these lists were discontinued so as to make space for other purposes, but we are now resuming their publication in a different and more useful form In the weekly summary, which in this issue appears on the last three pages of our text, the vacancies will be classified according to the nature of the appointment—e g, obstetrical psychiatric, or casualty In our advertisement columns which remain unchanged, the hospital appointments will, as before, be classified into senior and junior and then be arranged geographically The supplementary summary which is now to be provided should, however, make it far easier for readers to find the items in which they are interested The advantages of the existing classification will remain but the new and separate classification will, we hope, remove its disadvantages

A PRELIMINARY REPORT ON HE 1952 EPIDEMIC OF POLIOMYELITIS IN COPENHAGEN

ITH SPECIAL REFERENCE TO THE TREATMENT OF ACUTE RESPIRATORY INSUFFICIENCY

H. C. A. Lassen
M.D. Copenhagen
ROFESSOR OF EPIDEMIOLOGY IN THE UNIVERSITY OF OPENHAGEN; CHIEF PHYSICIAN, DEPARTMENT FOR COMMUNICABLE DISEASES, BLEGDAM HOSPITAL, COPENHAGEN

The 1952 epidemic of poliomyelitis in Greater Copenhagen has been the largest and most severe local epidemic ever recorded in Denmark.

ADMISSIONS

The metropolitan area of Copenhagen has a population of 1,200,000 people served by a single hospital for communicable diseases, the Blegdam Hospital. Between July 24 and Dec. 3 2722 patients with poliomyelitis were admitted to this hospital—866 with paralysis and 1856 without. In 316 of the 866 paralytic cases we had to resort to special measures, such as tracheotomy, artificial respiration, postural drainage, or combinations of these. The enormous load of severely ill patients is well illustrated by the fact that in four months we treated three times as many cases with respiratory insufficiency, paralysis of the ninth, tenth, and twelfth cranial nerves, and involvement of the bulbar respiratory and vasomotor centres as in the preceding ten years. At times we had 70 patients requiring artificial respiration, and we still have from 50 to 60 requiring it. To my knowledge nothing comparable has ever been seen in Europe.

The great number of severely ill patients pouring in made therapeutic improvisations necessary. During these months we have in fact been in a state of war, and at the beginning we were not nearly adequately equipped to meet an emergency of such vast proportions.

Fig. 1 shows that the epidemic culminated about Sept. 1. During the week Aug. 28–Sept. 3 our hospital admitted 335 patients or nearly 50 cases daily. The descending branch of the epidemic curve is, as usual, less steep than the ascending branch. At the time of writing, Dec. 7, the epidemic seems to be nearing its end. During the last two months the proportion of paralytic in relation to non-paralytic cases has grown steadily, but as a whole the ratio is 1 : 2. Naturally the number of patients admitted with non-paralytic poliomyelitis does not give an accurate picture of the true incidence of such cases in the epidemic area.

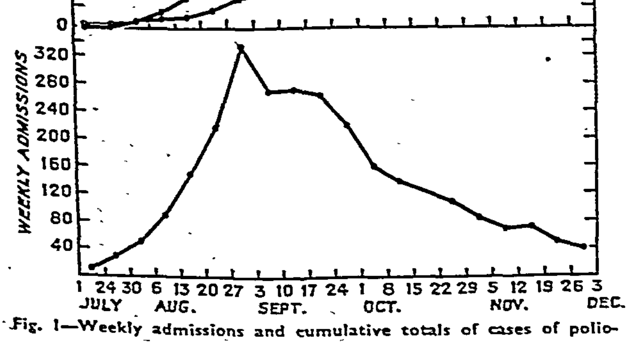

Fig. 1—Weekly admissions and cumulative totals of cases of poliomyelitis in 1952.

TREATMENT OF RESPIRATORY INSUFFICIENCY AND BULBAR DISEASE

In former years our therapeutic results in cases with respiratory insufficiency and involvement of the lower cranial nerves and the bulbar centres have always been very bad.

During the eleven years 1934–44 respirator treatment was used in 76 cases with a mean mortality-rate of 80%. Only cuirass respirators were used.

It is generally agreed that respiratory insufficiency of spinal origin is far easier to treat than respiratory insufficiency due to the involvement of the lower cranial nerves and the bulbar centres. Table I shows clearly the extremely grave prognosis of the pure bulbar and combined forms of respiratory insufficiency. With very few exceptions all our patients belonging to these groups died.

In 1948 we started using tracheotomy in all cases where it proved impossible to maintain an open airway because of pooling of secretions and aspiration into the lungs. In the U.S.A. this procedure seems to have had a beneficial influence on prognosis. In our hands this has not been so.

TABLE I—RESULTS OF RESPIRATOR TREATMENT OF POLIOMYELITIS 1934–44

Type of disease	No. of cases	No. of deaths
Respiratory paralysis without bulbar involvement	17	5 (*29%*)
Respiratory paralysis with bulbar involvement	51	48 (*94%*)
Respiratory paralysis of undetermined type	8	8 (*100%*)

Table II shows that all the patients treated by tracheotomy and with respirators died, whereas treatment with respirators alone had a somewhat better prognosis, 1 man and 4 children surviving. Of these 5 patients 4 had respiratory insufficiency of purely spinal origin, and 1 patient had transient slight impairment of swallowing.

Thus the prognosis of poliomyelitis with respiratory insufficiency was rather gloomy at the outbreak of the present epidemic in Copenhagen. At our disposal we had one tank respirator (Emerson) and six cuirass respirators. This equipment proved wholly insufficient when the epidemic developed into a major catastrophe.

Fig. 2 shows the admission dates of the 316 poliomyelitis patients requiring special treatment—i.e., tracheotomy, artificial respiration, postural drainage, and combinations of these forms of treatment. The chart exclusively comprises patients with respiratory insufficiency, paralysis of the lower cranial nerves, the respiratory or vasomotor bulbar centres or combinations of these forms of paralysis. During the epidemic tracheotomy was performed in about 250 cases. The indication for this operation was invariably stagnation of secretions in the upper airway, leading to inadequate ventilation. By far the greater number of the patients had simultaneously paralysis of the respiratory muscles. The 316 cases did not all come from the metropolitan area, because in recent years we have done much to centralise the treatment of such patients. Consequently fig. 2 includes 75 cases brought in from localities outside our usual area. These admissions account for the three peaks of the curve.

Until the last week of August we used the therapeutic methods practised in 1948–50, but during these terrible weeks the situation became increasingly critical. The

TABLE II—RESULTS OF TREATMENT OF RESPIRATORY PARALYSIS 1948–50

Treatment	Poliomyelitis						Polyradiculitis	
	Men		Women		Children		No	died
	No	Died	No	Died	No	Died		
Tracheotomy and respirator	9	9	4	4	1	1	3	3
Respirator exclusively	6	5	3	3	6	2	2	2

first month of the epidemic brought us 31 patients with respiratory paralysis and/or pharyngeal or laryngeal paralysis Of these 27 died, 19 within three days of admission The mortality rate was thus 85–90% At this point we consulted our anæsthetist colleague, Dr B Ibsen, and on Aug 27 the first patient was treated with the method which soon became our method of choice in patients with impairment of swallowing and reduced ventilation—namely, tracheotomy just below the larynx, with insertion of a rubber cuff-tube into the trachea, and manual positive-pressure ventilation from a rubber bag (bag ventilation)

The main features of the method are

(1) High tracheotomy with excision of a square opening in the anterior wall of the trachea

(2) Insertion of the widest possible rubber tube furnished with an inflatable cuff, so that the cuff closes the trachea, effectively preventing aspiration of stomach contents and secretions from the hypopharynx

(3) Repeated suction of the trachea and the main bronchi, and eventually repeated bronchoscopy, which is easy to do through the tracheotomy opening

(4) Postural drainage, frequent changing of position, and squeezing of the thorax, followed by aspiration through the cuff tube to avoid accumulation of secretions, bronchial plugging, and atelectasis

(5) Positive pressure ventilation (bag ventilation) with insufflation of a mixture of 50% oxygen and 50% nitrogen

Tracheotomy as early as possible is indicated in every patient in whom postural drainage and frequent suction cannot maintain an unobstructed airway and normal ventilation—i e, normal blood values of O_2 and CO_2 Most of these 316 patients had pooling of secretions in the hypopharynx and trachea, and a large majority were at the same time unable to cough or to swallow, and ventilation was inadequate

Quite a large number concurrently presented symptoms conventionally thought to be due to involvement of the bulbar centres Numerous biochemical tests have taught us that it is well nigh impossible to distinguish symptoms *usually attributed to the bulbar centres* from symptoms caused by retention of carbon dioxide, hypoxia, and shock

When manifest hypoxia and/or retention of carbon dioxide is present, eventually in combination with latent or clinical shock, prognosis becomes distinctly worse

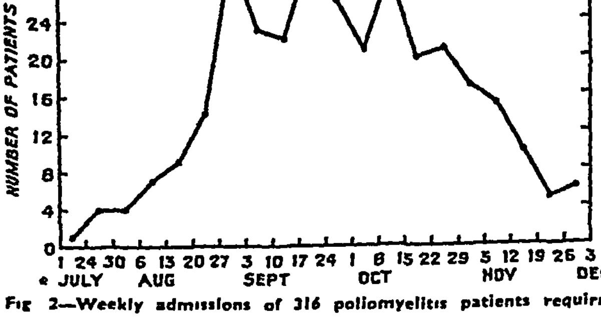

Fig 2—Weekly admissions of 316 poliomyelitis patients requiring special treatment

Early tracheotomy is therefore of decisive importa because hypoxia, retention of carbon dioxide, a vasomotor shock, even of short duration, may hav disastrous effect on nerve cells already damaged b virus infection

The first step of the operation is tracheal intubati through the mouth, thereby securing effective aspirati from the upper airway during the surgical interven and adequate insufflation of oxygen In our cases w have always used cyclopropane If this anæsthetic i not at hand, ether can be recommended Intraveno barbiturates should never be given as an anæsthe and sedatives should not be used, even in irratio and apprehensive patients, before adequate ventilati is secured *After this has been established, sedative* may be beneficial

The operation is done at the highest possible level, with excision of a square opening in the trachea If time permits, a suction catheter is introduced into the trachea and the main bronchi, and aspiration is begun during intermittent manual squeezing and pounding of the thorax to loosen secretions causing plugging and atelectasis of the lungs After this a rubber cuff tube is inserted and the cuff inflated to prevent aspiration of secretions from above At the same time the intubation tube is withdrawn It is important to use a cuff tube with the widest possible inner diameter and to secure the tube so that it does not slide down beyond the

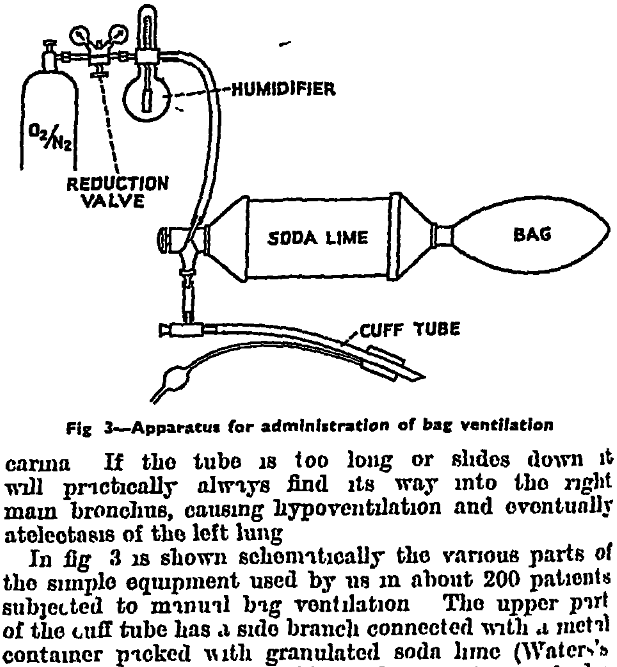

Fig 3—Apparatus for administration of bag ventilation

carina If the tube is too long or slides down it will practically always find its way into the right main bronchus, causing hypoventilation and eventually atelectasis of the left lung

In fig 3 is shown schematically the various parts of the simple equipment used by us in about 200 patients subjected to manual bag ventilation The upper part of the cuff tube has a side branch connected with a metal container packed with granulated soda lime (Waters's canister), from which a rubber tube goes to a cylinder containing equal parts of compressed oxygen and nitrogen A rubber bag is attached to one end of the canister, *and a valve at the other end permits regulation* of the pressure in the system The cuff tube is closed with a rubber stopper If aspiration is needed, the stopper is removed and a Tiemann's catheter is introduced mounted on a jet suctioning apparatus We have mostly used the ejector effect of a cylinder of compressed air, which is very effective and independent of electric power A good humidifier is essential otherwise incrustation of secretions may occur

The canister should be filled evenly with granulated soda lime of the best available quality to avoid insufflation of particles of soda lime into the upper airway causing irritation and increased secretion The canister must therefore be aired thoroughly by blowing a strong current of air through the container before it is used found American soda lime (Wilson) the most suitable the purpose. Unfortunately it is rather expensive, ting about 30s. daily for each patient.

If the precautions mentioned are followed, no ill effects observed. It is necessary to have two canisters for ch patient, and to change them every half hour. ter five hours' use the contents must be changed.

As will be seen from fig. 3, it is a closed to-and-fro stem similar to the one used in modern machines for neral anæsthesia, where carbon dioxide is effectively moved and an adequate supply of oxygen is secured hen the flow-meter registers 5–10 litres per minute. he bag is compressed from sixteen to thirty times per inute according to the patient's condition and age. he amount of oxygen mixture that should be given at ach compression of the bag depends on the thoracic xcursions and the general condition of the patient. The insufflation pressure must be short, and it is essential o release the pressure completely during expiration, so hat the least possible resistance to the passive elastic deflation of the lungs is maintained—i.e., atmospheric pressure. Expiration should therefore be twice as long as the insufflation. This is very important for reasons explained below. At all times the bag should only be partly full of gas. This can be regulated through the flow-meter and the valve at the top of the canister. We have several times measured the insufflation pressure when bag ventilation is administered correctly. It amounts to 20–30 cm. water. But the insufflation phase must be short.

The stomach should be emptied just after the operation, and in many cases it is advisable to insert an indwelling stomach-tube with continuous suction to avoid vomiting. Many of our patients had atonia of the stomach and paralytic ileus.

ADVANTAGES AND DISADVANTAGES OF BAG VENTILATION

Advantages

These are many and in our opinion far outweigh the disadvantages of the method:

(1) The equipment is easily procurable and inexpensive and needs no electric power.

(2) It is especially well suited for emergency treatment of patients before transportation to a treatment centre.

(3) Bag ventilation when correctly administered is superior to all other methods of artificial respiration in securing adequate ventilation. It counteracts the development of œdema of the lungs.

(4) The well-inflated cuff tube makes aspiration of secretions from the hypopharynx impossible.

(5) Aspiration through a catheter or a bronchoscope is easily done and with a minimum of discomfort to the patient.

(6) The respiratory excursions of the thorax produced are readily observable, and the recognition of atelectasis, pneumonia, and lung œdema by direct inspection, palpation, and stethoscopy is easy. X-ray pictures can be taken whenever necessary.

(7) The patient's position can be easily changed, and the thorax can be squeezed to facilitate effective aspiration through the cuff tube.

(8) Insufflation-rates and the volume of air pressed into the lungs by each compression of the bag can be adjusted for each patient. This is especially important when the patient is regaining spontaneous respiration, because at this stage it is possible to follow the often irregular respiratory efforts, assisting spontaneous movements by gently squeezing the bag or, later on, assisting the patient at every second, third, or fourth respiration.

(9) General nursing is greatly facilitated, as are injections, the taking of blood samples, and physiotherapy (hot packs) of peripheral paralysis and counteracting of contractions.

(10) The method has great psychological advantages. The patient is not encased in a cask, the notorious iron lung, with its collar either too tight or too loose to maintain the necessary intra-tank pressures. There is no danger of friction sores, which are so common when the cuirass respirator is used. All the members of the staff and the many visiting colleagues have been greatly impressed by the look of our patients receiving bag ventilation, by their calm, their apparent confidence, and total lack of apprehensiveness. The beneficial psychological influence of the person assisting the patient is often very great; it helps to keep up morale, creating confidence because the patient feels that somebody he knows well is always around, ready to help. This psychological assistance is especially important when the patient is regaining spontaneous respiration, and shortens the often difficult weaning period.

In our experience this new form of positive-pressure ventilation (bag ventilation) can be used continuously for months, at all times maintaining normal oxygen and carbon dioxide levels in the arterial blood. We have used it on some of our patients for more than three months. As the majority of poliomyelitis patients with respiratory insufficiency who do not die in the acute phase of the disease regain within three months sufficient spontaneous respiration to maintain adequate ventilation, it has in many instances been possible totally to avoid the use of mechanical respirators. This we consider a great advantage.

Disadvantages

The method has the following disadvantages:

(1) Particles of soda lime may be carried down into the bronchi and alveoli.

(2) When bag ventilation is administered continuously for weeks, there is a risk of emphysema.

(3) If bag ventilation is not administered correctly, the venous return may be reduced, leading to lowered cardiac output and a state of shock.

(4) Hyperventilation with subnormal carbon dioxide values may occur.

(5) The weaning period from positive-pressure ventilation is not infrequently difficult.

(6) The assistance of well-trained personnel all round the clock is essential and costly.

Provided the best available preparation of soda lime is used, and the canister is packed carefully and thoroughly aired before being used, the danger that particles may be carried down into the lungs seems to be more theoretical than practical. Nevertheless I am aware of the desirability of completely avoiding the use of absorbers and consequently we have experimented with different kinds of valves separating the ingoing and outgoing flow of air, and at the same time securing atmospheric pressure in the lungs during the major part of the respiratory cycle, thus hindering the venous return as little as possible. So far two types of valves seem satisfactory, having been in continuous use for long periods of time. Yet these valves are still in the experimental stage.

Potential dangers 2–4 may become manifest if bag ventilation is not administered correctly—i.e., the insufflation phase must be short. Danger 5 also depends on how the positive-pressure ventilation is done. In the hands of competent persons, well instructed in the inherent psychological aspects as well as in the technique of the method, difficulties in the weaning period can be greatly reduced.

As regards the expense of trained personnel, mechanical respirators also are very expensive—and, parenthetically, it is not at all certain which type should be preferred in the acute stage. Tank respirators of the newest American design equipped with positive intratracheal pressure attachment are hardly more effective in the acute decisive phase of poliomyelitis than the simple method used by us.

During several weeks we had 40–70 patients in our hospital requiring continuous or intermittent bag ventilation. To do this we have employed about 200 medical students daily. Their pay has been about 30s. for eight hours. The daily cost of the gas mixture per patient is about the same.

In the acute phase of bulbocerebral poliomyelitis several competing factors are involved, often difficult to diagnose and difficult to keep apart: these are virus disease of the central nervous system, hypoxia, retention of carbon dioxide, and vasomotor shock In most cases more than one of these syndromes are present, the patients presenting a mixed clinical picture Only careful clinical observation, supplemented by various biochemical tests, can guide us through this jungle of diagnostic difficulties and lead to a rational therapy

RESULTS

The poliomyelitis epidemic in *Copenhagen is only now* nearing its end Obviously it is therefore at the time of writing possible to give only *a brief account* of the therapeutic results

The first patient subjected to tracheotomy with insertion of a cuff tube in the *trachea and manual* insufflation of 50% *oxygen was treated on Aug 27 The method soon became our method of choice in all* cases with impairment of swallowing, pooling of secretions in the upper airway, and respiratory insufficiency This dangerous combination of symptoms occurred with unprecedented frequency and was present in the great majority of the 316 patients requiring the special forms of treatment previously mentioned

The point of reference is Dec 6, and the material presented comprises all patients admitted up to Nov 6 Some patients (31) admitted after this date are thus not included, but, as nearly all the deaths take place during the first few weeks of poliomyelitis, it is important to have at least a month's observation

The material includes five different types of treatment, all reasonably well defined, but it is only fair to emphasise that the patients treated with tracheotomy and bag ventilation included all those who were most severely ill

The five types and their therapeutic indications are

(1) *Tracheotomy and bag ventilation* —Pooling of secretions in the upper airway, impairment of deglutition, and insufficient ventilation

(2) *Tracheotomy and mechanical respirator* —Hypopharynx not entirely free from secretion, swallowing normal, and ventilation insufficient

(3) *Tracheotomy, eventually in combination with postural drainage and stomach tube* —Pooling of secretions in the upper airway, impairment of swallowing, and adequate ventilation

(4) *Mechanical respirator* —Respiratory insufficiency of purely spinal origin

(5) *Postural drainage and stomach tube* —Impairment of swallowing, without respiratory insufficiency

From the beginning of the epidemic up to and including Aug 25, 31 cases (group I) required special treatment as outlined above From Aug 26 to Nov 6, 250 such patients came into our hospital These patients are divided into five consecutive groups (II–VI), each comprising 50 cases in chronological order The composition of these groups regarding sex and age is very nearly equal

Table III shows that the mortality rate for these 250 patients, of whom the great majority were treated by tracheotomy and bag ventilation, was reduced from over 80% to about 40% representing about *100 lives* We are quite convinced that by far the greater part of these patients were saved by early tracheotomy combined with bag ventilation, and *further, that no mechanical respirator* could have taken the place of the bag ventilation with equally good results

TABLE III—MORTALITY-RATES

Group	Period of admission	No of cases	Died	Died within three days
I	July 21–Aug 25	31	27 (87%)	19 (70%)
II	Aug 26–Sept 8	50	26 (52%)	7 (27%)
III	Sept 8–Sept 27	50	24 (48%)	8 (33%)
IV	Sept 28–Oct 5	50	19 (38%)	10 (53%)
V	Oct 6–Oct 21	50	13 (26%)	7 (54%)
VI	Oct 21–Nov 6	50	18 (36%)	10 (55%)
Total II–VI		250	100 (40%)	42 (42%)

The table also shows a continuous drop in mortal rate, from group II to group V, from 52 to 26% Th probably is due to the fact that it naturally took s time before the treatment including adequate instruct of the hundreds of medical students employed—ab 1000 altogether—could be organised so that the b ventilation was correctly administered

Obviously it also took some time to learn the m effective ways of combating pulmonary complicatio and vasomotor shock Observing the decreasing mortality rate during the course of the epidemic, we naturall searched for evidence of decreasing severity of th bulbar cases but could not find any, a clinical impressi which is supported by the somewhat higher mortality rate in group VI The steadily increasing percentage of patients dying before the third day after admissio points the same way. During the month after Nov 6 we *treated 31 patients, who at a later date will be included in this series, with a death rate of 23% up to Dec*

The mean mortality-rate for 150 consecutive patients *(table IV)* treated by tracheotomy and bag ventilation was 47% However, *comparing the three groups shows a tendency towards lower mortality rates*—40%

TABLE IV—THREE GROUPS OF PATIENTS IN CHRONOLOGICAL ORDER TREATED BY TRACHEOTOMY AND BAG VENTILATION

Group	No of patients				No died			
	Male adults	Female adults	Children	Total	Male adults	Female adults	Children	Total
I	17	15	18	50	15	6	10	31 (62%)
II	17	14	19	50	8	5	7	20 (40%)
III	12	12	26	50	6	5	8	19 (38%)
Total	46	41	63	150	29	16	25	70 (47%)

The following data refer solely to the 250 patients *admitted between Aug 26 and Nov 6 after* the introduction of bag ventilation

Of 55 men treated by tracheotomy and bag ventilation 31 (56%) died, *of 43 women* 17 (40%) died, and of 74 children 29 (38%) died The mortality-rate for males thus seems greater than for women and children This is in accordance with our clinical impression that more men than women and children were critically ill, but a great proportion of the patients treated by tracheotomy and bag ventilation were in a very bad state on admission

Only 11 patients were treated by tracheotomy and respirator from the time of the operation Of these 5 died, all of them children

By tracheotomy alone, or in some cases combined with postural drainage and continuous suction through a stomach tube, 33 patients were treated—2 men, 5 women, and 26 children Only 1 of the adults died, whereas 9 children died, in most cases probably owing to severe encephalitis, which seems to have been rather common among the children this year *10 patients* were exclusively treated in respirators None of these patients had impairment of swallowing, and their respiratory insufficiency *was purely spinal* With 1 *exception* all survived Finally 20 patients with impairment of deglutition only and with pooling of secretions in the upper airway but with adequate ventilation were treated by postural drainage and with an indwelling stomach tube They all survived *5 patients* were moribund on admission and died before treatment could be instituted

CONCLUSIONS

I do not think that this method is ideal It certainly needs to be perfected, and we are working at improving it However, in comparison with results formerly obtained in our hospital, it seems fair to regard the results as satisfactory in the circumstances

It should emphasise that the results of treatment of spiratory insufficiency and paralysis of the lower cranial rves in poliomyelitis have been favourably influenced early tracheotomy, with insertion of a tightly fitting bber cuff tube ; repeated aspiration and bronchoscopy ; ostural drainage and stomach-tube ; and bag ventilaon. In our hands this method has reduced the ortality-rate from above 80 to about 40%.

Parliament

Economies in Hospital Staffing

IN the House of Commons on Dec. 19, on the motion for the adjournment for the Christmas recess, Mr. ARTHUR BLENKINSOP called attention to a circular[1] recently sent by the Ministry of Health to hospital boards with regard to economy in man-power. The Opposition, he said, would certainly seek the earliest opportunity of raising the matter much more fully.

The circular would embitter relations between management committees and regional boards. There was no doubt that the proposals in it would affect most unfairly the position of one hospital as against another. The Opposition had no objection to a comprehensive review of hospital staffs ; indeed, that had been going on for some years, and a great deal of progress had been made : but the circular provided for an immediate return of all existing hospital staffs, and for what amounted to a freezing at that wholly arbitrary figure.

Mr. Blenkinsop said that by the operation of this circular hospital management committees were being stripped of some of the last vestiges of their authority. This would cause many who had given most valuable voluntary service to doubt whether they could usefully continue their work. Did this proposal mean that the Ministry was in process of disbanding these committees ? In any case, matters within the competence of the committees would now be transferred to the regional boards, and matters within the competence of the boards would now be subject to the decision of the Ministry. The Ministry was the last authority which should have the power of dealing with these detailed administrative questions. Mr. Blenkinsop had no objection to the fixing of an agreed establishment figure beyond which the staff could not be increased without authority ; but the Ministry was taking an arbitrary figure. Why had it given up the view that proper establishments should be worked out and agreed on, and that these should be made compulsory, if necessary, subject to review by higher authority ? This day-to-day review of a whole host of cases would block up the whole machinery. The regional boards were saying that they would need more staff to provide the information for which the Ministry was asking. There was bound to be delay in this procedure, which might mean the loss of people best qualified for the jobs.

Miss PATRICIA HORNSBY-SMITH, parliamentary secretary to the Ministry of Health, said that the planned programme for dealing with the staffing of the hospital service had been going on for some time. It was essential that progress should be made in this matter, particularly in view of the disparity between the staffing of hospitals. This circular would speed up the process and show where the gaps existed. Far from making the position worse, it would make it better because the staff would be obtained where they were most needed. The Minister had made it quite plain that it was his intention to allow shortages of staff to be made up. Of 435 regional boards, boards of governors, and management committees, 264 had now been visited ; in 180 cases establishments had been determined for administrative and clerical staff, and in all these there had been no engagement of extra staff without previous consent. The Opposition ignored the disparity of staffing. In one of the teaching hospitals there were 102 on the nursing and midwifery staff to every 100 staffed beds : in the average general hospital there were 53 nurses and midwives to every 100 staffed beds ; and in the mental hospitals there were 15 on the nursing staff to every 100.

In England Now

A Running Commentary by Peripatetic Correspondents

OUR tea club is an old and respected institution. The tea is manufactured from two vast kettles in a picturesque array of teapots in a subterranean cavern in the basement, and is distributed by safe hand on trays to the parched occupants of the periphery of the building. It is our experience, however, that the safer the hand the slower the feet, and by the time the third storey is reached not a few of the original calories have escaped into the circumambient atmosphere. Further, during the vicissitudes of the journey the destination of the cups, originally crystal clear, becomes sullied with uncertainty, so that the member at the end of the round never knows whether he is to receive a cup bearing the inscription "Lab. 5," "Cleaners," or, more simply, "Peggy." The other day we were interested to find ourselves drinking out of a cup with the stark label "Rat linseed."

In 1939 the iron hand of war reached down into our basement and dealt the tea club a blow from which it has never fully recovered. Even now the sugar gives out towards the middle of the third week of the ration period, and those of us who are accustomed to protect our livers from the effects of tannic-acid absorption by the judicious ingestion of sucrose spend an unhappy few days. Our genial and courteous Animal Man is occasionally in a position to alleviate our distress by impounding—without their knowledge or permission—some of the monkeys' sugar. During the Black Days he frequently brings in a lump with the comforting assurance : "It's all right, sir, they'll never miss it."

In the circumstances, however, it is not surprising that there should be mutterings among those who are not placed so fortunately adjacent to the animal house, and a splinter group has actually been formed to drink illicit coffee. They post lookouts in the corridors, and their source of carbohydrate is a jealously guarded secret, but it is suspected that much is due to their foresight in coöpting a visiting American. Once a week we have a departmental tea-party, at which both the orthodox and the seceders partake of cake ; and our conscientious accountant has worked out the fraction of the tea-club subscription which non-members have to pay to qualify for two slices. Even so, unscrupulous dissenters have been observed lingering behind after the party is over to pick up a few crumbs which they have not paid for. Feeling runs high, especially as it has recently been found necessary to raise the subscription, and it is felt that a stand should be taken on the matter. Since the recent cold spell, however, we have lost our confidence that a stand would be successful, for there are indications of disunity in the highest places. Twice in one week our President-Secretary-Treasurer has been discovered guiltily drinking 'Bovril.'

* * *

The African Dingaka Association, composed of witch-doctors from the Union of South Africa with delegates from Rhodesia, Swaziland, Bechuanaland, and Basutoland, has been holding a convention, five hundred strong, in Pretoria. The medicine-men turned out in full ceremonial rig, with head-dresses of beads and feathers, jingling bracelets, and ear-rings, and their garments decorated with bones, shells, and beer-bottle tops. Their president, Lukus Somo, said they had gathered to reaffirm their faith in the traditional methods of their ancestors, and in order to obtain government recognition of their claim to official status. They take a dim view of non-members who practise their profession, and dub them "quacks and illiterates." They have voted £10,000 to start a medical school in Johannesburg at which students of their craft may be trained in genuine witch-doctoring and herbalism.

The South African Government has recently banned the advertising of magic remedies, made from insects, reptiles, and "human ingredients" and guaranteed effective against evil spirits, witchcraft, and supernatural forces. Anyone advertising *muti*, as this sort of medicine is called, may be fined £50 and sent to gaol for six months. The Dingaka Association want this ban removed for genuine practitioners, but they do not explain why they still use this type of remedy, nor how they obtain the "human ingredients"

* * *

"Next please," said the porter John, who had been holding a magazine upside down, rose to his feet, pulled his jacket down, straightened his tie, arranged his handkerchief smoothed his hair, straightened his tie again "Come along, sir," said the porter, "he's waiting" That did it Our *restraint vanished* and we crowded round the door "Is he in a good *mood*? Has he ploughed many? Has he had his afternoon tea?" The porter smiled enigmatically and John was led into the outer darkness We gathered round the table

"Wasn't long with the last one"
"Never is if you're good"
"Long ones are for the doubtful"
"I hate being at the end of the alphabet"
"At least you know what he *asked in the morning*"
"That's the trouble Do you know what he *asked yesterday*? What dose of neostigmine would you use in a myasthenic crisis?"

There was a silence "What *is* the *dose*?" said a strangled voice They say that books should never be brought to an oral examination, but somehow they always seem to appear Glances were cast uneasily in their direction and there was a soft shuffling of feet Suddenly panic seized us, books were flung open, leaves turned, pages sought "Neostigmine 'stigmine," voices intoned in a pagan chant

"Here it is," cried Smith "Neostigmine 0 5 to 1 mg in a 1 2000 solution given intramuscularly The methylsulphate should be used" There was an ominous *silence* "How could anyone remember a dose like that," said Smith at last "It's impossible" "Don't worry He won't pip you on a thing like that You never get pipped on doses" George spoke with authority—this was his third attempt We cheered up

"What about yesterday?" said Smith
"Well," I said coldly, "what about yesterday?"
"He asked Jones the dose of aloin Jones said 5 grains" Smith's voice became a broad impersonation "'With that dose, Mr Jones, the only thing you would fail to pass would be this examination'"

The door opened "Next please" I stood up, straightened my tie, adjusted my handkerchief, smoothed my hair "Come along, sir," said the porter, "he's waiting"

* * *

I have never really forgiven medical *advertisers for* making me buy my *own stamps*, *now they* are all licensees who only pay for returns But their annual bounty in the form of diaries and calendars deserves at least a word of thanks Perhaps they would take it in the form of a few kindly hints

First, don't call me madam, that is no way to address an old rugger blue And you haven't heard of the fellowship I got ten years ago I don't think much of your blotting-paper either One sneeze and it is lodged irretrievably behind the mantelpiece Larger and double-sided, please I'm far too busy *to notice* which side I'm using Nor am I impressed by Continental-looking reprints—e g, *Hodenschmerz on* "Nips for Neurotics" True the language is English, but the typeface is that of the *Zeitschrift fur Bunkwissenschaft* And please make it snappy Do you expect me to read a page or more of single-spaced typing with no headings? And you medical publishers, why so sheepish about the price of your wares? They are far too dear, anyway, and it's the same old wolf whether you say "Price £5," "This costs £5," "This is priced at £5," "This is to be had for £5," or "This sells at £5" (Liars! You know as well as I do that doctors stopped buying books years ago!)

Letters to the Editor

FATAL APPENDICITIS

SIR,—Mr Skyrme Rees's large and interesting ser of cases (Dec 20) was so well documented and examine that one could wish he had gone a little further a listed the causes of death in the fatal cases

His definition of group III (appendix abscess) i difficult to understand Were all these 935 cases reall "among those which were not operated on," and, if so from what strange series of misfortunes did 81 of them di

I am not sure that the *mortality*-rate can be reduced by advocating earlier operation, nor do I believe that the "expectant or conservative" treatment of uncomplicated appendicitis occupies any large place in our minds Delay, when it occurs, is usually the result of sheer neglect or mistaken diagnosis My own efforts at diagnosis have been so humiliating that I have long abandoned any attempt at recognising acute appendicitis and I have confined my endeavours to deciding whether an acute abdomen exists or not, and, if it does and requires operation, I have tried to hazard a guess as to the best place to make an incision This diagnostic humiliation has been somewhat tempered by evidence of a similar fallibility on the part of my associates, and by the fact that of some 500 patients whom I have treated for genuine acute appendicitis, only 2 have died—a mortality rate for all types of case which approaches the "irreducible minimum" to which Mr Rees refers None of my cases died from pulmonary embolism, in spite of a belief in the heresy of putting sick patients to bed and keeping them there until they feel better

I hold that this satisfactory state of affairs is a result of the early inculcation of sound and sensible principles for dealing with this condition, of later association with a surgeon who had strong leanings towards conservatism and of working in areas where the standard of general practice is high If you, Sir, will bear with me, I should like to enunciate the principles which I was taught or have picked up as I went along, because I think their correct application is the only way to reduce the mortality of this condition Needless to say, they should be applied in hospital, not in the home

(1) Forget the diagnosis of appendicitis and concentrate on recognising the presence or absence of an "acute abdomen" If there is doubt in this matter, it is better to wait (a few hours) and see, than to look and see If the patient gets worse, operate If he gets better or develops the measles, then it would be folly to operate

(2) Patients with a tender lump (appendix abscess) do not form one clinical group, but two Those with a slightly tender lump and a long history (7 days or more) must not be operated on—not even if they are children or old people Nowadays, with antibiotics, all these lumps resolve without incision, and it is quite unnecessary to starve the patients or put them on an intravenous drip Those with a very tender lump and a short history—say, 3 days—must be operated on forthwith, and the appendix should be removed

(3) Use a McBurney (or Rutherford Morison) incision when the tenderness is maximal in the flank Use it, if you like, in young males whose symptoms are mild Never be tempted by its cosmetic advantages to use it at any other time In all other cases and *especially* if there is a lump, use a low paramedian incision This will allow adequate exploration and treatment of patients in whom the diagnosis has been at fault, it will allow the uncontaminated areas of the abdomen to be packed off before the exploring finger releases a gush of pus, and it will allow visual and digital contact with the pelvic floor—essential for finding, sucking out and draining an associated pelvic abscess A few patients will develop an incisional hernia, but it is comforting to reflect that this complication is peculiar to the living

(4) Always look for a pelvic collection of pus by retracting the lower end of the wound outwards, introducing the half hand into the depths of the pelvis, and displacing the small

wel medially. This manœuvre often reveals a large and suspected quantity of pus.

(5) Drain all "perforated" cases, and those in which emostasis has been imperfect, and any others if there is oubt in one's mind. A residual abscess in the right iliac ssa will always find its way out along a drainage track, but a clean stitched case it will probably require a second peration, or may even find a path of lesser resistance leading o the general peritoneal cavity. Drains do not carry infection nto wounds made to expose the gall-bladder, the thyroid—r the appendix.

(6) Distinguish very clearly between postoperative patients with soft distension of the abdomen and a satisfactory general ondition, and ill-looking patients with firm abdominal distension. Give parenteral fluid to the latter, never to the former; and this will achieve a great saving of salt and water.

(7) If the patient develops early mechanical obstruction, a considerable degree of surgical skill is about to be required. Be very wary of the "modern" advice to perform ileo-transverse colostomy through a separate incision. The distended small bowel pushes the transverse colon up into the epigastrium, and it is impossible to identify individual loops of small bowel. Reopen and extend the wound, and at once eviscerate as much small bowel as is required to obtain adequate exposure. This evisceration will not kill the patient and, if it is to be done at all, it is best done quickly. Whether the bowel can be returned or not is a matter for earnest discussion between surgeon and anæsthetist. It can be kept in place, while the abdominal wall is sutured, by a large piece of corrugated rubber. Through and through sutures may be required.

I hope that Mr. Rees will agree with my expansion of his brief comments on the minutiæ of operative technique, and with the bearing I suggest they have on his subject.

Barnet General Hospital. V. J. DOWNIE.

SIR,—Of the 7 fatalities in Mr. Skyrme Rees's group I, where inflammation was limited to the appendix, no less than 6 were due to pulmonary embolism. Out of the total of 1958 cases this gives the very high proportion of one death from this cause in every 326 patients. Possibly in the earlier cases in the series the importance of some form of support to the heels was not realised? It is now recognised that thrombosis usually originates in the veins of the calves, which must be kept off the table during any operation which might be followed by a pulmonary infarct or embolism. I have recently described[1] a simple support which serves as a constant reminder to the theatre staff that a heel support is imperative.

The treatment of cases in group III, in which an abscess was present, leaves the reader in doubt as to the precise nature of the treatment, for it is stated that "most abscesses were treated by drainage only," and subsequently we are told "these cases are among those which were not operated on." The crux of the matter is whether cases of appendicular abscess were submitted to operation or treated conservatively. The fact that out of 935 cases no less than 81 died—a mortality of 8·7%—suggests immediate operation, because with expectant treatment and removal of the appendix some three months later, the mortality is in the region of 1%. A typical example is to be found in the figures of Sworn and Fitzgibbon,[2] who analysed 2126 cases admitted to St. Thomas's Hospital, and found that the mortality of immediate operation in cases of appendix abscess to be 7·9%, as compared to 0·68% in cases treated expectantly. These figures, and many others which indicate similar results, point to one of the measures which will reduce deaths from appendicitis—namely, discrimination in dealing with cases of localised infection, as opposed to what the late Sir James Berry called "the hard and fast rule, adopted by so many, of operating at any stage—a rule so easy to follow, but often so disastrous to the patient."[3]

I agree that Mr. Skyrme Rees is technically correct in stating that the term "conservative treatment" should not apply to cases of appendicitis as opposed to those of peritonitis, in case doctors may be misled into treating on expectant lines inflammation which is limited to the appendix. However, during some thirty years of consulting practice I have never met a practitioner who deliberately "cooked" a diagnosed case of acute appendicitis when surgical measures were available, in the hope that resolution might occur.

London, W.1. MCNEILL LOVE.

RESECTION FOR PULMONARY TUBERCULOSIS

SIR,—It appears to me that both your leading article (Dec. 6) and Dr. Brailsford's letter (Dec. 27) over-simplify the problem of treating pulmonary tuberculosis. You refer to a paper by Ryan et al.[1] which proposes an interesting conception, but which is unlikely to prove to be of universal application. It is of course possible that the course of the disease is different in the U.S.A., but in any event the observations quoted are based on a small series of 30 patients treated surgically. In this country we are not so often able to reduce the disease to a purely nodular condition.

However this may be, surely Dr. Brailsford misses the point when he says (as in effect he does) that surgery cannot be expected to help the sufferer from pulmonary tuberculosis, or that patients can overcome the disease more easily without surgery than with it?

No-one, Sir, will deny that many small and some extensive tuberculous lesions will heal either spontaneously or with simple medical treatment. But neither can it be denied that many tuberculous lesions lapse into a chronic state, with healing in some places and extension in others. Chemotherapy will not then make any appreciable difference to the course of the infection, which may be expected to result in the death of the patient sooner or later.

Surgery is not indicated in pulmonary tuberculosis (or, indeed, in any other condition) until it is seen that healing is unlikely by less drastic means. I take it that Ryan and his colleagues, in common with other workers in this country and elsewhere, are attempting to prevent the breakdown which is so distressing a feature of this disease by removing the lesions which appear unlikely to heal permanently after a considerable period of sanatorium treatment. It is just here that resection of the affected areas of the lung is proving to be of greatest worth as a technical method, but it is a matter of experience that the patients do best when they have been made as fit as possible before operation by medical treatment on the commonly accepted lines. The patients will usually only remain fit in the sheltered conditions of a strictly ordered sanatorium routine. If they would be fit for normal life without danger, there would be no indication for operation. Working on these lines, the question of infectivity of the sputum becomes of secondary importance, for although the persistence of tubercle bacilli means that the patient is a danger both to himself and to others, their absence is a less important prognostic point than the demonstration of instability of the lesion by observation, or of some other indication of the unlikelihood of healing—e.g., size (a diameter of 2 cm. or more) or persistent cavitation.

If Dr. Brailsford is upset by the report of "30 wedge or subsegmental resections," I am afraid that he will be profoundly shocked if he hears that Mr. F. Ronald Edwards, myself, and our colleagues in Liverpool can report a series of more than 700 lung resection operations for tuberculosis. We feel convinced, nevertheless, that the extended use of this method has resulted in a great change for the better in the patients' prospects, and that

2. Sworn, B. R., Fitzgibbon, G. M. *Ibid.* 1932, 19, 410.
3. Berry, Sir James. *Lancet*, 1932, i, 1027.

---

1. Ryan, B. J., Medlar, E. M., Welles, E. S. *J. thorac. Surg.* 1952, 23, 327.

there are fewer patients needing repeated admissions to hospital as a result

Chemotherapy is extremely valuable, but its place is still limited, when and if a sufficiently potent antibiotic becomes available to arrest tuberculosis medically, thoracic surgeons will be pleased to be able to rest a little! There is no panacea, and if surgery is needed, neither resection nor thoracoplasty is universally applicable I am sure that Dr Brailsford would agree with me that the object of treatment is to restore the patient as nearly as possible to a state of good health by the safest and quickest means Ryan and his colleagues, and those with whom I have the pleasure of being associated in Liverpool, believe that it is an advance to resect the lesion which is unlikely to heal while it is still possible to do so, although we here have no great faith in the technique of multiple wedge resections

I hope that Dr Brailsford will believe me when I say that surgery (including lung resection) is often beneficial in pulmonary tuberculosis, that it has a logical basis, and that it often produces a dramatic improvement in the general health, and I can assure him that surgery is not undertaken unless it appears necessary for the reasons I have given The healed lesion is of no concern to the surgeon, but the failure to treat adequately the unhealed localised lesion is of the utmost concern to the patient because of the tragic consequences of the development, sooner or later, of chronic cavitation which may be difficult or impossible to cure

Liverpool B J BICKFORD

SPLENOMEGALY IN SCARLET FEVER

SIR,—Dr O'Reilly asks (Dec 20) whether others have had the same experience as he in finding splenic enlargement in scarlet fever

While in charge of an isolation block in a military hospital in Egypt during the late war, I recorded the prevalence of splenic enlargement in various infectious diseases The prevalence in three of these infections was as follows

	Total cases	Splenomegaly	
		No	%
Scarlet fever	42	3	7 1
Tonsillitis	81	5	6 2
Diphtheria	221	14	6 3

In all cases malaria was excluded by blood films and in all cases the spleen was no longer palpable on discharge

Department of Child Health,
University of Sheffield R S ILLINGWORTH

PRECISION IN DIAGNOSIS

SIR,—I agree with Dr Todd (Dec 27) that it is often quite impossible to attach a precise textbook diagnosis to a patient's disability and at the same time maintain one's professional intellectual integrity, and I find myself in sympathy with his plea for a less rigid system of *nomenclature in medical documents*

I would suggest, however, that a cause of error, confusion, and misunderstanding more fundamental and *more serious than the mere attaching of officially accept*able disease labels to patients, lies in the assumption that behind these labels there are disease entities each possessing a genuine, intrinsic, if vague, reality The belief that diseases have independent existence is implanted in us by the teaching we receive as students and is encouraged by our textbooks, our journals, and all forms of professional communication so that the whole pattern of our thought and speech is influenced by it, and that the belief is accepted without question is implicit in the way we talk about "discovering" or "describing" diseases (diseases which by the way, we have not defined) or in the way we pass over without comment such phrases as "the biological properties" *of this or that disease—phrases which imply that the* diseases in question have existence in their own right

The problems raised by this hypostatisation of diseases are not purely abstract theoretical or linguistic, for example, he is a singularly fortunate or forgetful doctor *who cannot recall that any of his patients have suffered* as a result of his preoccupation with diagnostic labels and his misconception of their significance—or lack of *significance To some extent, too, the failure to appreci*ate that disease names do not represent real *things* causes disease statistics *to* be less accurate than they *might be, though probably the search for names as* such has a more serious effect in this way, as Dr Todd seems to imply

It is difficult to see what cure there can be for this state of affairs unless it be in an increasing awareness of the extent and danger of this fundamental misconception

Falkirk RONALD G HENDERSON

COUGH MIXTURES

SIR,—I was interested to see in an annotation[1] a reference to the use of inhalations of carbon dioxide (in a 5% mixture with oxygen), and to Banyai's description of this inhalation as an "effective expectorant, which not *only* stimulates respiration and increases bronchial peristalsis but 'liquefies mucopurulent inflammatory exudates'"

Dr Herxheimer and *Dr McAllen* mentioned carbon dioxide favourably in their subsequent letter,[2] in which they were good enough to refer to my work on expectoration I would only add that in my view it is unlikely that bronchial peristalsis plays any part in expectoration Anatomically it is improbable that a peristaltic mechanism exists in the alveolar musculature (the myoelastic tissue of Macklin) Many investigators have postulated a kind of reflex by which expectoration is always associated with peristalsis, but I have been unable to demonstrate any such mechanism radiologically I found instead that the expulsive force came from reinforcement of the normal respiratory effort, *rather than from* added peristalsis It follows that carbon dioxide increases expectoration simply by stimulating respiration

University of Berne,
Switzerland T GORDONOFF

RESEARCH INTO INTESTINAL POLYPOSIS

SIR,—For more than twenty five years the research department of St Mark's *Hospital*, assisted by an annual grant from the British Empire Cancer Campaign, has been collecting information about the inheritance, pathology, and *treatment of familial intestinal polyposis* (polyposis intestini)

More than fifty families have been investigated, and in each case a complete family pedigree has been constructed A special follow-up department has been organised to keep in touch with all these polyposis cases and *their relatives, of whom more than one thousand are* now included in the hospital records It would be of great assistance to the further development of this work *if doctors who know of other cases of generalised intestinal* polyposis would be good enough to send me the names and clinical details of such patients, having obtained their permission to do so This would enable me to trace linkages between new cases and families already investigated If any such linkage could be discovered *either now or at a later date, I should inform the doctor* at once but should not of course communicate with the patient unless the doctor wished me to do so

I am signing this letter because I am responsible for organising this research, but I should like it to be understood that all the surgical staff of St Mark's Hospital are actively cooperating in this investigation

COLLEGE OF GENERAL PRACTITIONERS

SIR,—For many general practitioners Christmas will ave been brighter this year than any since the war, nd this not only because some of us have larger bank alances than for many years past.

It can have been no accident that the announcement f the completion of the spadework by the steering ommittee was made before the New Year but after 'Danckwerts." So let us all respond to the good news f the birth of the new college by joining at once as foundation members, by paying our joining subscription promptly, and—one more thing—by making a gift to the college of a substantial amount of money to raise a foundation endowment fund.

Money is power, and we all want the new college to be powerful for our good. Money given now is more valuable than money given in six months' or a year's time. Money given by members of the profession who are not general practitioners will be an especial encouragement to the college, and it would be into such an endowment fund that these donations could best be paid.

I have sent a cheque for what is to me "a substantial amount of money" to the secretary of the new college, asking him to pay it into, or use it to start, such a foundation endowment fund; and I appeal to every member of the profession to consider whether he can also do this as a birthday present to the new college. I enclose my card, but you will appreciate that I would prefer to sign myself as

ONE OF MANY ?

PAROTID TUMOURS

SIR,—Mr. Payne will probably like to be reminded in reply to his query (Dec. 20) about the operative diagnosis of parotid swellings that Dr. Redon is coming over from Paris in May to open a discussion on the treatment of tumours of the parotid gland at the surgical section of the Royal Society of Medicine. British surgeons will look forward with great interest to an authoritative account of parotidectomy by a speaker whose experience of the subject is almost certainly unrivalled.

With regard to the value of histology, our article was not concerned with the subleties of histological subdivision of the mixed parotid tumour group. We merely indicated that histology might be necessary to separate such widely different pathological entities as, for example, mixed parotid tumour, adenolymphoma, inflammatory swellings, and carcinoma, which clinically at the moment of presentation might be indistinguishable.

London, W.1.

DAVID PATEY
BERNARD H. HAND.

CHEMOTHERAPY OF TUBERCULOSIS

SIR,—May we correct an erroneous impression which may have been given by your account last week of the Royal Society of Medicine symposium on the chemotherapy of tuberculosis.

Referring to our interim statement on the Medical Research Council trials of isoniazid, you state that "Preliminary results . . . suggest that on the whole isoniazid plus streptomycin will prove the most valuable combination" (when compared with streptomycin plus P.A.S. and with isoniazid alone); "it has shown itself strikingly superior to streptomycin plus P.A.S. or to isoniazid alone in the type of case where chemotherapy is expected to give little benefit."

Our actual report was that clinically "there is a suggestion that streptomycin plus isoniazid is somewhat more effective than either streptomycin plus P.A.S. or isoniazid alone, but that the difference is not striking." There was no suggestion of "striking" superiority. We stressed that the correct placing of the combination of isoniazid plus streptomycin in chemotherapy will depend largely on the bacteriological results, which are not yet available. Until this information is forthcoming it would be unwise to regard streptomycin plus isoniazid as superior to other treatments.

PARTIAL THORACIC STOMACH IN CHILDHOOD

SIR,—I feel sure there will be many engaged in children's medicine who will feel grateful to Professor Smellie and his colleagues (Dec. 13) for affording us the information about these 112 small children whose main symptom was vomiting and who were shown to have a short œsophagus or so-called partial thoracic stomach.

During the twenty-five years which have elapsed since Sheldon and Ogilvie [1] published their cases of œsophageal obstruction in early life many such cases have been reported, but it would seem that we are still in doubt about the causation of this so-called partial thoracic stomach. I believe with Professor Smellie that the condition in its early stages is much more frequent than the records of the more advanced condition, when obstruction and ulceration are present, would suggest.

I wonder whether Professor Smellie can tell us whether this common and interesting condition is still considered to be a congenital defect, and whether it has ever been found post mortem in a neonate. Is this a condition which may lie latent from birth without causing vomiting ? I should have thought that were it a congenital abnormality its presence would have been occasionally reported by our radiological colleagues when carrying out barium-swallows and follow-through examinations for conditions other than vomiting. Also can we be told whether any of these children were re-examined radiologically after the cessation of vomiting, and if so do the results disclose a disappearance of the partial thoracic stomach ?

Meanwhile, even at the risk of being told that this is undoubtedly a congenital abnormality, I would like to ask whether Professor Smellie thinks it at all likely that the condition may after all be due to some of the causes of vomiting which have been discussed by Dr. B. S. B. Wood,[2] of which persistent underfeeding is an important one. For some time now I have wondered whether the condition has any connection with a hungry infant's persistent efforts to return its food and try and enjoy it again while waiting for the ending of the four-hour interval laid down by child-health authorities. Such efforts might over a period of weeks tend to pull, push, or balloon the stomach into the thoracic cavity via the hiatus and thus produce the partial thoracic stomach. This possibly may be thought to be an over-simplification. At any rate it might be worth while to feed these small infants so that they are fully satisfied and, if partly or completely artificially fed, can obtain the food easily by sucking from a boat-shaped bottle with a very easy teat, to prevent them being waked from sleep for a feed, and to make sure the child is fully satisfied within ten or twelve minutes. The still-prevalent teaching of the mother by midwife, maternity unit, and teaching centre that the neonate should take twenty minutes over a feed is certainly asking for trouble.

Leeds.

WILFRED VINING.

⁂ This letter has been shown to Professor Smellie and his colleagues, who reply:

"Professor Vining raises a number of important and pertinent points to only some of which definite answers can be given.

"As symptoms referable to the anomaly frequently arise within twenty-four hours of birth it is difficult to avoid the conclusion that the disease is congenital. In so far as our own records go, a partial thoracic stomach has not been encountered in a neonate post mortem We have some evidence, however, which suggests that the condition can remain symptomatically latent from birth

---

[1] Sheldon, W., Ogilvie, A. T., *Arch. Dis. Childh.* 1929, 4, 347.

[2] *Lancet*, 1952, i, 28.

"It is understandable that unsuspected cases are not likely to be accidentally discovered on routine barium-meal examination Experience has taught that, even when the disorder is definitely suspected and when special attention is directed to the lower œsophagus, radiological confirmation of the lesion may be far from easy If during the screening no œsophageal reflux occurs, visualisation of the supradiaphragmatic portion of the stomach may not be possible A number of our children have been re-submitted to radiological study when symptoms have abated, some have retained the anatomical abnormality, but in others it has become difficult to be certain of this once reflux has ceased to occur

"Professor Vining's suggestion that the herniation of the stomach through the diaphragm might be caused by the regurgitating efforts of the starved and hungry infant is ingenious and thought-provoking In our view, with which Dr Wood concurs, there is no evidence to suggest that under-feeding is a factor in the production of a partial thoracic stomach From further analysis of infantile vomiting, Dr Wood[1] considers that in a number of his infants with 'persistent vomiting of uncertain origin' the cause is gastro œsophageal incompetence"

CONGENITAL DEFECTS FROM MATERNAL RUBELLA

Sir,—Having recently seen a fatal case of encephalitis complicating rubella in a child aged 6 years, I view with mixed feelings the suggestion by Mr Robin (Nov 22) that there is every justification for recommending that all girls should be exposed to rubella before leaving school

Bulawayo Southern Rhodesia J Charles Shee

VITAMIN B_{12} IN PRACTICE

Sir,—In your leading article of Dec 13 you state that "at the moment there is no way of distinguishing before treatment the patient who has a vitamin-B_{12} deficiency from one who has a folic acid deficiency" This unqualified statement is untrue Though it is not possible to distinguish between these two deficiencies by hæmatological methods, this can be done by microbiological assay of vitamin B_{12} in serum using *Euglena gracilis* var *bacillaris*[2] With this method it is found that in patients with vitamin B_{12} deficiency the serum B_{12} concentration is very low—usually less than 50 μμg per ml In normal subjects and in patients with megaloblastic anæmia due to folic acid deficiency, the serum B_{12} concentration is always above 100 μμg per ml[3]

In all patients with untreated pernicious anæmia low serum B_{12} concentrations have been found In patients with megaloblastic anæmias other than pernicious anæmia (associated with gastro-intestinal conditions or pregnancy) the pre-treatment serum B_{12} concentrations were variable, being either as low as in pernicious anæmia or within the normal range Patients with low serum B_{12} concentrations all responded to treatment with vitamin B_{12} those with normal concentrations failed to respond to vitamin B_{12} but responded to either folic acid or folinic acid Occasionally, deficiency of both factors has been present, in these patients the serum B_{12} level was low but the response to vitamin B_{12} alone was incomplete

Though the method is at present a research technique, these results indicate that microbiological assay of vitamin B_{12} is of value in the differentiation of megaloblastic anæmias It must be noted, however, that occasional samples of serum (about 6%) contain some substance not considered to be vitamin B_{12} or to be hæmopoietically active, but with growth-promoting action for the test organism Such sera may give falsely high results If more than one pre treatment serum sample is tested, however, the method becomes very reliable and a definitely low serum B_{12} concentration can be confidently accepted as proof of severe vitamin B_{12} deficiency in the body

TERRAMYCIN

Sir,—A recent experience demonstrated the effectiveness of terramycin in salmonella infections—a subject discussed by Mr Ritchie and Dr Phillips (Dec 13) Two children, now aged 5 months and 9 months, passed stools containing *Salmonella typhi-murium* for 10 and 12 weeks respectively Repeated courses of succinyl sulphathiazole, penicillin aureomycin and chloramphenicol failed to produce more than an odd negative stool even during actual treatment

It was found that a 4 μg tablet of terramycin in the culture-plate medium inhibited the growth of the organism *On giving an elixir of* terramycin (125 mg t d s for the younger child and q d s for the older child), their stools were negative 36 hours after treatment began, and remained negative for the week of treatment and for the week following They were then discharged from hospital No change in feeding or environment was made during this time

This exclusive and striking in vitro and in-vivo action suggests that terramycin may be the drug of choice in this type of infection

Ingham Infirmary,
South Shields

A J Watson

SHORTAGE OF JUNIOR HOSPITAL STAFF

Sir,—I read with interest the letters and your annotation on this subject in the issue of Dec 20

The whole object of doing house jobs is to gain clinical experience, either as the first rung in the specialist ladder or as a prelude to general practice It is quite obvious that the numbers available should bear an ascertainable mathematical relationship to the number of general practitioners and specialists

It is also apparent that unless the present position materially alters there will not be enough juniors to undertake those duties not requiring specialist training Surely the answer is the permanent appointment of general duties officers to fill the gap, with pay and emoluments comparable with those obtainable in general practice

London W 1

Guy Rigby-Jones

THE AFFERENT-LOOP DISTENSION SYNDRO

Sir—Professor Wells and Mr MacPhee (Dec 20) point out that great care should be taken to distinguish between the afferent and efferent loop syndromes The distinction is important, but the time to recognise unduly sensitive bowel is before the operation of partial gastrectomy

They also write "When a patient has typical jejunal symptoms but does not show the patterns of efferent loop hypermotility as described by Glazebrook, *the afferent* loop syndrome in a *forme fruste* should be suspected I am sure however, that many, if not the majority, of cases of efferent loop hypermotility are caused by (*a*) the powerful stimulus of a distended afferent loop, and (*b*) the damming back of pH regulators and digestive ferments in a distended afferent loop

Lessening, or virtual disappearance, of afferent loop syndromes with the passage of time does not me that the condition has righted itself These sad ar ndernourished individuals can make adjustments by estricting their diet and taking light work, while their pathetic bowels, once vigorous, lose the power to make ffective protest.

---

[1] Wood B S B Astley R (in the press)
[2] Ross G I M *J clin Path* 1952 5, 250
[3] Mollin D L Ross, G I M *Ibid* p 129

Professor Wells and Mr. MacPhee, by focussing attenion on the afferent loop, have made a substantial ontribution. It is to be hoped that the conception of 'neurotic attacks"[1] will now cease to bedevil the erious and growing problem of the post-gastrectomy syndrome.

Harrogate. A. J. GLAZEBROOK.

PITUITARY EXTRACT IN OBSTETRICS

SIR,—The report of the Emergency Obstetrical Service in the Manchester area[2] is disturbing since it reveals that whole posterior pituitary extract (the preparation mentioned was 'Pituitrin') is still being used in domiciliary obstetric practice.

We firmly believe that whole posterior pituitary extract should not be used in obstetrics since it contains not only the oxytocic but also the toxic vasopressor factor. *Admittedly the purified oxytocic fraction* (injectio oxytocini, *B.P.*) contains some vasopressor substance, but its vasopressin content per unit activity is not more than 1/20 of whole extract (injectio pituitarii posterioris, *B.P.*); hence the latter is much more toxic. Vasopressin constricts the coronary vessels and produces impairment of the action of the heart. In a woman who has already lost blood this may produce shock or even death.

Obstetric Unit, University College Hospital Medical School. W. C. W. NIXON.
Department of Pharmacology, University College, London, W.C.1. H. O. SCHILD.

BUTAZOLIDINE

SIR,—To the reports of toxic effects following the administration of butazolidine I would like to add two observations which I have not seen described in publications in this country. They seem noteworthy among others I have seen, which include the usual digestive, cutaneous, purpuric, and hæmaturic incidents, and three cases of jaundice, apparently obstructive. I cannot at present give their proportional incidence, as they have occurred in three hospitals and in private practice.

One patient went into left ventricular failure complicating generalised œdema. This complication was mentioned by Stephens et al.[3] and Steinbrocker et al.[4]

Another patient had characteristic œdema with extensive patches of œdematous erythema on limbs and trunk, progressing to peeling of the face and limbs and maculate purpura on the trunk, after taking one tablet only. There was no evidence that this patient had had the drug before.

I may add that I am taking the drug myself with much relief of the pain of my rheumatoid arthritis.

Hove, Sussex. W. A. BOURNE.

SUFFERING FROM PERNICIOUS ANÆMIA

SIR,—Patients with pernicious anæmia suffer more at the hands of doctors than the failure to reassure them mentioned by Dr. Todd (Dec. 20).

Recently an applicant for entry to the teaching profession was medically examined and found physically fit in all respects. She gave a history of pernicious anæmia, successfully treated; and this was entered on the official form as a minor condition not likely to interfere with the performance of her duties. Her application for entry to two teachers' training colleges has been rejected on medical grounds, because of pernicious anæmia.

Had she not told the examining doctor about her anæmia it would not have been diagnosed clinically; so she is being penalised for giving an honest history, and her whole career is jeopardised unfairly. What remedy has she?

If I had to be ill I should rather have "pernicious" anæmia than "benign" tertian malaria or a "benign" adenoma. Would it not be better to give up the adjective "pernicious" and talk about addisonian anæmia, as many already do?

Giggleswick,
Settle, Yorks. D. P. LAMBERT.

Public Health

Deaths During the Fog

THERE were 4703 deaths registered in Greater London in the week ended Dec. 13 when, during the first half of the week, smoke-laden fog covered most of the area.[1] The figures for the preceding two weeks were 1902 and 2062, and deaths in the corresponding week of 1951 were less than a third of this year's total. Deaths from influenza and pneumonia increased from 89 in the week ended Dec. 6 to 380 in the week of the fog: and many more deaths from respiratory or cardiac disease were referred to coroners than in normal weeks.

First reports on the chemical content of the fog indicate that there was more sulphur dioxide and carbon in it than usual. The Ministry of Health suggests that "these increases are for the present better regarded as a measure of fuel consumption, principally coal, rather than as an index of 'atmospheric vitriol.'" The Ministry says that an analysis of the information given on the death certificates is being made, pathologists' reports are being examined, and further investigation of the constituents of the fog and smoke is in hand. No conclusions can be reached until this work is completed.

Saving Fuel in Hospitals

The Northern Ireland Hospitals Authority, examining the reasons for the rising cost of the hospital and specialist services, has been paying particular attention to means of reducing fuel consumption in its hospitals. The authority's report for the year ended March 31, 1952, says that an engineer and a stoker-demonstrator have been visiting some of the hospitals in Northern Ireland to test the fuel-burning plant, and to make recommendations for improving efficiency. It is estimated from their reports that expenditure on fuel in the general hospitals visited (1740 beds in all) can be cut from £29·3 per bed per annum to £23·6—an annual saving of £9900. The changes needed to save this sum are being made wherever possible. All the hospitals in Northern Ireland will eventually be dealt with.

Appointments

BOOTH, R. W., M.R.C.S.: appointed factory doctor, Cinderford district, Gloucester.
BRENTNALL, T. D., M.R.C.S.: appointed factory doctor, Oakham district, Rutland.
LOVE, S. H. S., M.B. Belf., D.A.: consultant in anæsthetics, hospitals of Belfast H.M.C.
MILLAR, J. H. D., M.D. Belf., M.R.C.P.: part-time consultant neurologist, Royal Victoria and Claremont Street Hospital, Belfast.
O'RIORDAN, J. P., M.B. Dubl., D.P.H.: port M.O., Dublin.

Colonial Medical Service:

BEDELL, F. E., L.M.S.S.A.: district M.O., Windward Islands.

Obituary

CHARLES PORTER

M D, B Sc Edin, M R C P E

Dr Porter who died on Dec 15 at the age of 79, was medical officer of health of St Marylebone from 1910 until his retirement in 1939.

He was educated at the Royal High School, Edinburgh, and in the Universities of Edinburgh and Freiburg He graduated M B in 1896, and took the M D (with high commendation) in 1902 From 1902 to 1906 he was lecturer on bacteriology in the University of Sheffield

During his long term of office in St Marylebone he was closely concerned with the preparation and supervision of many of the borough's plans for improving the health of its people, and he contributed especially to the plans for slum clearance, housing, and maternity and child-welfare services (several of which were the first of their kind under municipal schemes)

His work, however, was not restricted to local public-health matters He was president of the Society of Medical Officers of Health and chairman of the council of the Royal Sanitary Institute, of which he was also vice-president He served upon many departmental committees and at the invitation of the Minister of Health, took part in international health conferences in other countries He was an honorary fellow of the American Public Health Association, and among other bodies of which he was for many years a member were the General Nursing Council for England and Wales, the Council of the Queen's Institute of District Nursing the Royal Sanitary Institute and the Sanitary Inspectors' Examination Joint Board, and the Worshipful Company of Plumbers, whose Master he was for the current year

Dr Porter was a well-known writer on public health and preventive medicine For ten years he was honorary editor of *Public Health* the official organ of the Society of Medical Officers of Health and, apart from works on many different aspects of hygiene, he was joint author of a standard textbook on sanitary law

He leaves a widow, and a son and three daughters by a former marriage

H A B writes

'Charles Porter, with his short, stocky, monocled figure and inexhaustible energy, was a great personality An outstanding authority on preventive medicine, his reputation and influence extended far beyond St Marylebone which he served as medical officer of health with such distinction for nearly 30 years He took a foremost part in grappling with the many public health problems of his day, and he was inevitably to be found in the midst of controversies ranging from epidemiological research to the severely practical and revolutionary 'one pipe' system of drainage for buildings

"He possessed a keen journalistic sense and was a prolific writer—indeed, his only hobbies were reading and writing Apart from being author, editor, commentator, and reviewer, he contributed a weekly page to a public health journal for many years, never missing an issue even though he might be in America for three or four months taking part in an international health officers' course or reporting abroad to a world health organisation Most of his work was set to type from his own neat handwriting, and he had an uncanny knack of writing just enough to fill the space allotted to him

'In addition to his work for D P H students, he was keenly interested in the training of sanitary inspectors and health visitors, and his name was familiar to a host of these officers who studied under him and eventually found him a lively and sympathetic, but searching examiner He excelled as an after dinner speaker, and was greatly sought after for the aptness of his comments and the brilliance of his wit

Charles Porter did not suffer fools gladly, but for those prepared to work hard with him he was an inspiring and fearless leader, and a delightful and helpful friend"

ARTHUR CANT

M B Birm

Dr Arthur Cant who died on Nov 30 when he was within a few days of his 80th birthday, was a well-known Midland general practitioner

Educated at King Edward's School, Birmingham, he studied medicine at Mason's College, Birmingham, and qualified M R C S in 1895 He graduated M B at Birmingham when the university was granted its charter in 1901 After house-appointments in Birmingham and Kidderminster he settled, more than fifty years ago, in Coleshill Warwickshire He soon became not only the doctor but the trusted friend of the widespread rural community and, working to the end of his long life, he retained to the last the affection of his patients

GEORGE GRANT

M A, M B Aberd

Dr Grant, who died on Dec 19 at his home in Dunbar was in practice in Cardiff for the first thirty years of the century Born at Grantown-on-Spey in 1867, he was educated at Fordyce Academy and at the University of Aberdeen where he graduated in arts and medicine The five years after qualification were spent in assistantships in various parts of England, and he settled in Cardiff in 1900 A friend writes

"He set his face against all innovations in principle, though he was usually delighted with any which he was persuaded to accept Thus he ran his large practice without benefit of motor car or telephone, and till he retired he made all his visits on a bicycle He knew his patients through several generations I remember him greeting a woman in 1930 in Crewe station with great affability, and afterwards saying 'I don t remember her name, but her son had pneumonia in 1919 when he was six' He refused to join the National Health Insurance scheme in 1911, and, perhaps partly because of this much of his work was done among mothers and children he became especially successful in advising on the rearing of delicate babies His Welsh patients accepted his plain speaking, for he was, after all, a Scot, and they valued his honesty conscientious care, and infinite patience He was never in a bad temper and seldom—and then justly—angered He was ready to enjoy everything and to see good in everyone In his retirement he made new friends, who were no longer also his patients, and many people in Dunbar would say 'It always does you good to meet Dr Grant'"

Mrs Grant survives him with three daughters

Notes and News

THE WORLD'S CHILDREN

THE 20th century, Arnold Toynbee said last year in the *New York Times*, "will be chiefly remembered not as an age of political conflicts or technical inventions, but as an age in which human society dared to think of the welfare of the whole human race as a practical objective." Let us hope he is right. It is, at all events, a more encouraging appraisal of our century than most. And at least the United Nations International Children's Emergency Fund can claim to have attended strictly to this practical objective. Its life story is briefly outlined in a pictorial record [1] of some of the children it has helped. Born in December, 1946, it started work immediately—bringing food, clothing, and medicine to children in devastated parts of Europe. In recent years it has gone farther afield, to poor and undeveloped countries in Africa, Asia, Latin America, and the Eastern Mediterranean. Here its task has been to teach, at the very simplest level, something of the proper care of infants and children, and of childbearing women. And since so much of a child's welfare depends on what goes into his belly, UNICEF has played the part of a benevolent milch-cow in these many countries, providing fresh milk when it is possible, dried milk when it is not, supplying dairy equipment and milk-drying plants, and encouraging people to increase their own milk-supply. In Yugoslavia, for instance, UNICEF collaborated with the government in a comprehensive milk conservation plan, providing much of the equipment while the government supplied buildings, transport, and labour. Much of the labour was provided, in Sarajevo, by volunteers who helped to dig the foundations and put up the buildings for the milk plant. The same kind of help has been given by UNICEF in eight other European countries, and to peoples in Central and South America and the Eastern Mediterranean. Some populations are so sick from endemic diseases that they have not the heart or strength to grow themselves adequate food. UNICEF has supplied the D.D.T. for antimalarial campaigns in some 26 countries. Teams go through the countryside spraying the houses, protecting millions from the disease, and making it possible for vast areas to be brought under cultivation. This means there is more for the family to eat, because the men are better able to work in the fields. Mass-scale B.C.G. vaccination has also been begun in some parts of the world, and UNICEF has provided penicillin for government-administered campaigns in countries where yaws is rife. Maternity and child-welfare clinics have been started in many countries; and UNICEF helps to start midwifery training centres, and provides midwifery kit—which gives status—for those midwives who complete their training.

UNICEF believes it has already helped some 60 million children, but estimates that some 500 million are in need of help. The size of the problem is therefore much greater than our recent verse [2] suggested. The income of UNICEF comes voluntarily from governments, peoples, and individuals throughout the world. In its six years of life it has helped children in 76 countries, giving only such supplies and equipment as the country itself cannot provide; and its contribution is in every case matched or more than matched by the government of the assisted country. Thus a contribution to UNICEF is at least doubled in value by the time it reaches the children; and in addition, of course, *bis dat qui cito dat*. Not many investments, nowadays, give such good returns. The address is UNICEF, United Nations, New York.

GEOGRAPHICAL PATHOLOGY

THE International Society of Geographical Pathology has for its object the systematic study of diseases and their distribution and characteristics throughout the world, and it investigates pathological problems upon a common plan, with the aim of throwing light upon the pathogenesis of disease conditions by comparing observations made in widely different regions. The inquiries cover morbid anatomy and histology, clinical manifestations, biochemistry, bacteriology, virology, serology, and epidemiology, and include the diseases of wild and domestic animals. At its first meeting in Geneva in 1931 the society discussed cirrhosis of the liver; at Utrecht in 1934, arteriosclerosis; at Stockholm in 1937, the anæmias. During the war the activities of the society were interrupted, but through the enterprise of Prof. F. Henschen (Stockholm) representing morbid anatomy, Prof. L. Michaud (Lausanne) representing clinical medicine, and Prof. F. C. Roulet (Basle) also a morbid anatomist, the society met again in Liège last July, under the presidency of Prof. J. de Josselin de Jongh and the chairmanship of Prof. J. Firket (The Hague) to discuss hepatitis. The proceedings of the meeting are to be published in *Documenta de Medicina Geographica et Tropica*, of Amsterdam.

A VIGOROUS CENTENARIAN

IN the 19th century, when there were still plenty of innominate diseases about, the great natural historians of medicine had their sharp eyes open for symptoms, and their inquisitive minds in a ferment of analysis and synthesis. *Guy's Hospital Reports*, which completed its hundredth volume in 1951, might almost be called the nature notebook of many of these brilliant observers. In an article now reprinted, Mr. R. C. Brock [1] recalls some of the long list of clinical triumphs recorded in it. Astley Cooper described here the necropsy findings in two cases of aneurysm, in one of which he had ligated, eighteen years before, the common carotid, and in the other, thirteen years before, the external iliac artery; Thomas Williamson King first ascribed to the thyroid an internal secretion; Bright gave his most extensive (though not his first) account of his disease in these pages; Addison's disease was generally accepted as an entity largely because Sir Samuel Wilks, one of the editors, repeatedly wrote up cases in the *Reports*. Addisonian anæmia, too, was given much attention in the journal; and Babington, in 1841, recorded there, for the first time, the relation between chorea and heart-disease, quoting observations by Addison. Hodgkin discovered his disease in 1832, before the *Reports* had begun; but the eponym was conferred in its pages in 1865. Taylor, author of the *Manual of Medical Jurisprudence*, contributed his classical articles on poisoning, and on tattoo marks as evidence of personal identity; Gull provided the first account of anorexia nervosa, discussed the significance of fatty stools and mesenteric gland disease, and described the condition we now call myxœdema. Wilks noted in its pages the association between aneurysm and syphilis, and showed that this infection produced other internal lesions; and this remarkable man also described for the first time lymphatic leukæmia (under the name "leucocythæmia"), bacterial endocarditis, and alcoholic peripheral neuritis. Chevers (anticipating Pick) published the first clear clinical account of constrictive pericarditis in the *Reports*, and Cooper Foster described the first gastrostomy done in Great Britain. The long record runs on into this century, when Hurst, one of the most dynamic of editors, published in the *Reports* 75 articles between 1908 and 1939, many of them on his work on the alimentary canal. Ryle, too, described his studies of the digestive system, made with Izod Bennett; and Ryle's tube appeared in these pages in 1921.

A few odd gaps in publication explain the fact that the *Reports* is older than its century of volumes suggest; but like all the truly mature it is not ashamed of its age—which is in fact a green 116. Mr. Brock has roused the echoes of the thundering *Reports* of the past; and we may reasonably expect the bombardment to continue. Meanwhile a modest salvo, in congratulation, seems in order.

HOSPITAL LIBRARIES

PATIENTS' libraries were discussed at a meeting of the medical section of the Library Association on Dec. 12, at which Mr. A. Lee, chairman of the section and librarian of the Liverpool Medical Institution, presided.

Miss Sheila Moore described the evolution of hospital libraries, whose purpose, she thought, was to provide a means of escape from the monotony of ward routine, to distract from pain, and to act as a link with the outside world. The St. John and Red Cross Library took a large part in the story; but the resolution of the Library Association in 1930, recommending hospital authorities to provide libraries under the control of trained professional librarians, had not been widely adopted. However, the Ministry of Health memorandum of 1950 suggested that "a library service should gradually be developed to a high standard in all hospitals." During recent years a few hospitals, mainly large mental hospitals, had appointed professional librarians to their staffs. Sometimes the librarian was expected to organise social events and other activities; and, while Miss Moore did not see how one person could do the two jobs and provide a really efficient library service, these appointments were a step in the right direction She thought that these dual appointments were made simply because the money could not be stretched to meet the need for two people to do two different jobs. Describing the library of which she is in charge at St Thomas's Hospital, London, Miss Moore said they were hoping to see what results could be achieved by a full-time hospital library They had had a great deal of help from public, university, and special libraries for example, they had borrowed from the School of Oriental and African Studies books in Urdu, Hindu, Turkish, and Arabic, and a request from a patient for a life of Bonnie Prince Charlie in Gaelic was met within four days from Inverness Public Library The St Thomas's library now had 8000 volumes and was still growing A new trolley had been designed to take the books to the wards, similar in principle to the picture postcard turn tables used by stationers

[1] *Guy's Hosp. Rep.* 1952, 101, 235.

Mr Gilbert Barker, librarian of the St John and Red Cross Hospital Library, said that all who took up this work found inspiration and satisfaction in it The essentials were a love of people and books and the toughness of an ox, for the combination of mental and physical work was tremendous

Mr W J Bishop, of the Wellcome Historical Medical Library, pointed out that Soranus of Ephesus, a first century physician, had encouraged patients to acquire varied reading matter that was easy to hold By the 18th century many large hospitals had libraries for patients and by the 19th century it was exceptional, particularly for mental hospitals, not to have them Crichton Royal, founded in 1842, soon had 5000 books, and Edinburgh Royal Infirmary had 3000 volumes in the 1890s Of course the libraries did not compare with the modern ones, among other things, patients used to complain that the books were almost entirely of an uplifting and devotional character

DANGEROUS DRUGS ACT

On Dec 8 3-methoxy-N-methylmorphinan came under the terms of part III of the Dangerous Drugs Act, 1951 It is now therefore illegal to import or export this drug except under licence, and the Home Office has power to make regulations designed to prevent its improper use The provisions apply to the three forms of the drug (dextromethorphan, levomethorphan, and racemethorphan), to its salts, and to any preparation, mixture, extract, or other substance containing the drug

University of Cambridge

The following associate lecturers have been appointed Mr Christopher Parish (thoracic surgery), Mr L M Rouillard (plastic surgery), Dr Brian Donnelly (radiology), and Dr W Paton Philip (diseases of the chest)

On Dec 13 the degree of M CHIR was conferred on R N Ticehurst, and the degrees of M B, B CHIR were conferred by proxy on Hamish Nicol

University of London

The title of professor of dental surgery has been conferred on Dr F C Wilkinson, director of the Institute of Dental Surgery, British Postgraduate Medical Federation

At a recent examination for the academic postgraduate diploma in medical radiology (diagnosis), J M Lockie and Edward Mercieca were successful

University of Sheffield

Dr D R Wood has been appointed to the senior lectureship in pharmacology, Dr T M Abbas to the senior lectureship in obstetrics and gynæcology, and Mr J S D Bacon, PH D, to the senior lectureship in biochemistry

iversity of Bristol

At recent examinations the following were successful:

M.B., Ch.B.—K. J. Barker, Marjorie E. Barton, N. G. Blackwell, R. Bollen, Ann E. Booker, J. C. Causton, Anne W. Christie, an M. Claremont, Barnett Ginsberg, Alan Moore, I. W. Palmer, N. Prichard, P. H. Sherwood, H. S. Smith, D. W. G. Stone, E. Tovey, H. A. P. Walker.

niversity of Liverpool

At recent examinations the following were successful:

M.D.—H. G. Frank, D. R. W. Haddock, A. Jolleys, R. S. ones, P. P. Newman.

M.Ch.Orth.—C. J. R. Conacher, W. C. Lawrence, M. Lunz, Page, A. Rahim, E. H. Strach, J. G. Stubbs, K. J. M. Watson.

D.M.R.T.—R. V. Samapurnavanitya.

D.P.H.—R. Muscat.

University of Edinburgh

On Dec. 19 the following degrees were conferred:

M.D.—*Alick Cameron.

Ph.D. (in the faculty of medicine).—*S. W. Bibile.

M.B., Ch.B.—F. E. Adderley, Jean M. Bell, George Beveridge, eean Bheenick, D. A. Brown, J. D. Cormack, J. T. Dixon, A. G. Fraser, A. H. French, A. K. Fulton, Alice B. E. Gray, Ann S. Haig, R. W. Hall, D. L. N. Haultain, P. A. Hood, Isabel J. Huggan, A. D. L. Hunter, J. L. Hunter, R. D. Jones, P. L. Kennedy, D. S. Lyon, R. B. Macpherson, R. S. Maini, D. J. B. Makins, N. E. L. Margetson, A. R. Mather, Q. S. Moore, Elizabeth M. Munro, W. S. Munro, G. M. Ogilvie, T. G. Paterson, W. B. Paterson, J. M. Robertson, Ian Shaw, Catherine J. Tulloch, R. P. M. Urquhart, Bryan Willis, F. F. Wilson, W. M. Wilson, Elizabeth J. Q. Wood, J. C. Yellowley.

*In absentia.

The following diplomas have also been awarded:

D.M.R.-D.—F. G. T. Beetham, D. A. E. Dewar, R. K. McFarlane, D. A. R. Ritchie.

D.M.R.-T.—A. R. Lyons, K. S. Preston, J. B. McEwan.

The Crichton research scholarship has been awarded to Dr. Evelyn A. C. Skinner, and the Hastilow research scholarship in rheumatism to Dr. W. R. M. Alexander.

University of Durham

On Dec. 19 the following degrees were conferred:

M.B., B.S.—B. T. M. Aboko-Cole, Kathleen D. Blackett, Q. A. Bynoe, Robert Chambers, Dorothy H. Cooper, Ann E. Crabbe, E. P. Daniels, C. C. Day, G. MacA. Dowson, K. W. H. Fenwick, F. M. Fyfe, Edith P. Gilbertson, J. C. Gilbertson, J. C. Gilmour, H. E. Harper, A. G. Larson, Moira Lickley, C. R. Markham, Jean A. Rosenstein, I. M. Telfer, Archibald Turner, I. A. R. Watson, Alan White.

University of St. Andrews

In recent examinations the following were successful:

M.D.—R. A. B. Rorie.

M.B., Ch.B.—Keith Davies, Colin Gunn, Julia C. Izzard, R. M. Kelly, Eileen M. Key, E. D. McEwan, H. R. Simpson, Elizabeth M. Stephen.

University of Glasgow

On Dec. 19 the following degrees were conferred:

Ch.M.—R. B. Wright (with high commendation).

Ph.D.—T. W. Wikramanayake.

M.B., Ch.B.—G. J. Addis, J. C. Baird, A. T. Bowie, Mavis J. Bowyer, Z. D. Brodie-Mends, D. B. Campbell, G. R. Carroll, Nathaniel Chazan, Joan A. Cree, G. L. W. Cunningham, A. F. Davidson, J. McK. Davie, J. A. Docherty, Angus Dodds, T. E. S. Fergusson, Morag B. P. Fernie, H. F. Frame, D. A. S. Fraser, Annice H. G. Gillespie, A. K. Gillies, Joyce E. J. Hassan, Hugh Hatrick Thomas Hetherington, W. E. I. Healy, D. E. Jardine, J. S. Kennedy (with commendation), W. McG. Kirk, S. J. Lepper, Mrs. David G. Lindsay, Eileen M. MacColl, Francis McCormack, Alasdair Macdonald, Jean Y. MacDougall, A. G. R. McFadyen, James McGlone, S. W. McGowan, Barbara S. Maclean, Donald Macmillan, T. E. Macnamara, A. S. MacPhail, Ian Macpherson, Ferguson McRae, Robert Meldrum, C. M. Morton, R. O. Nkeaka, A. R. Pate, Robert Reid, H. G. Robinson, E. D. T. Ross, George Ross, G. B. Ross, Joyce W. Russell, J. H. Shearer, W. M. Shovlin, Allan Sinclair, J. D. Stevenson, Sheena G. MacD. Stuart, John Sutherland, A. S. Taylor, A. S. Thomson, Dorothy E. Walby, Ethna A. Walshe, Doris M. White, J. G. Young, Jean McI. Young.

The diploma in public health was awarded to James McGovern.

Royal College of Surgeons of Edinburgh

At a meeting of the college on Dec 17, with Prof Walter Mercer, the president, in the chair, the *following were admitted* to the fellowship

W A Anderson, M I Anwar, Mohammad Anwer, Agnes U Campbell, B M Corkill C M Couves R M Gaitonde *G B Gibson*, R W. L Heddle J H Hofmeyr Y M Kim I C S Knight, G B Ong, *J N* Ravalia, John White

W D MacLennan was admitted a fellow in dental surgery

Fellowships in Clinical Research

The Medical Research Council invite applications for a third series of *fellowships in clinical* research, tenable at centres in the United Kingdom during the academic year 1953–54 (see *Lancet*, 1951, i, 536) The awards will be made for one year in the *first instance, and* will be renewable annually in approved cases up to a maximum of three years in all Candidates must be medically qualified and clinically experienced, and should preferably have worked in a department where clinical research was in progress They will be invited to submit their proposals about the type and place of work, but the council will be *glad to help successful* candidates to find suitable departments or *laboratories* Applications must be sponsored by the head of the appropriate department in the candidate's university or medical school Forms of application may be had from the secretary, Medical Research Council, 38, Old Queen Street, London, S W 1, to whom they must be returned not later than March 1

South African Research Fellowship

Applications are invited from doctors registered in South Africa for the 1953 award of the Eli Lilly medical research fellowship The value is $250 a month for 12 months, plus travelling expenses to and from the U S.A The closing date for applications is May 15 Further details can be had from Dr L Eales, hon- secretary of the selection committee, Cape Town Post-Graduate Medical Association, P O *Box* 2980, Cape Town

---

Emergency Bed Service—*In the week ended last Monday*, applications for general acute cases numbered 1379 The proportion admitted was 93 03%

Dr Macdonald Critchley has been elected corresponding foreign member of the Academie de Médecine of France

EOGRAPHIC VARIATION IN NATURALLY ACQUIRED TUBERCULIN SENSITIVITY*

LYDIA B. EDWARDS
M.D. Johns Hopkins
CHIEF OF FIELD STUDIES

CARROLL E. PALMER
M.D., Ph.D. Minnesota
DIRECTOR

TUBERCULOSIS RESEARCH OFFICE, WORLD HEALTH ORGANIZATION, COPENHAGEN

ALMOST all proponents of B.C.G. vaccination agree that c.g. need not (or should not) be given to persons already fected with tuberculosis. B.C.G. infection is believed be effective only if it precedes infection with virulent ibercle bacilli. This doctrine governing the use of c.g. seemingly involves no serious theoretical problem: tuberculin test is made; if the tuberculin reaction is egative B.C.G. is given, if positive, B.C.G. is not given; nd few would challenge the view that tuberculin testing hould be a reasonably efficient way to separate previously ifected from non-infected persons in a population.

Turning from theory to practice, however, one finds an mazing variety of recommended tests, dosages of tuberulin, kinds of tuberculin, criteria for distinguishing ositive from negative reactions, and so on. From the tandpoint of vaccinating or not vaccinating with B.C.G. hese differences may or may not be important. But they ust affect the validity of daily decisions in practical uberculosis work regarding the identification of persons reviously infected with tuberculosis.

The present paper deals very broadly with the problem f using the tuberculin test to obtain information on aturally acquired tuberculin allergy and the use of such aterial as an index of the prevalence of tuberculosis nfection in a population. The report is based on pre-accination Mantoux tests made by the field staff of he Tuberculosis Research Office of the World Health rganization, Copenhagen, in connection with large-cale studies on B.C.G. vaccine and vaccination carried ut during the past several years. It is the third in a eries of papers illustrating how routine health-service rogrammes can contribute to the solution of fundaental problems in medical science, if the work is carefully planned and done with at least reasonable accuracy.

In the course of selecting children to receive B.C.G. n this series of studies, pre-vaccination Mantoux tests ave been made on about 40,000 children in Denmark, exico, Egypt, and a rural part of South India. All of he tests were given with the same lot of P.P.D. tuberculin RT XIX-XX-XXI),† and the work, though carried out in idely separated countries, was performed with a high egree of uniformity by personnel who had had intensive raining in field techniques and procedures. Most of hem have, at some time, worked under close supervision n the research programmes in Denmark. Both a weak nd a strong dose of tuberculin were used, thus providing unique and fairly large body of data for the study and omparison of the pattern of natural tuberculin sensitivity f children living in four different parts of the world.

TUBERCULIN SENSITIVITY IN DIFFERENT COUNTRIES

From this material we present here only the results of pre-vaccination tests with 10 and 100 T.U. for about 10,000 children in Denmark, 1700 in Mexico, 3000 in Egypt, and the results of 5 and 100 T.U. tests for 2500 children in South India. The criterion for giving the 100 T.U. test, and B.C.G. vaccination as well, was failure to react with at least 6 mm. of induration to the initial 10 T.U. test (5 mm. to the 5 T.U. test). The 100 T.U. test played no part in the selection of children for vaccination: it was given only to obtain additional information on tuberculin sensitivity before vaccination.

The tuberculin sensitivity of these children is probably fairly representative of each of the four different areas; B.C.G.-induced allergy had not yet distorted the pattern of natural allergy in any of the populations, and the few who had been vaccinated were identified and excluded from the material. The Danish children attended 225 municipal schools in a rural part of Jutland; the Egyptian group comprised pupils in 10 municipal schools in the Delta area and 3 schools in Luxor in the Upper Nile; the Mexican children attended 3 schools for working mothers in Mexico City; and in South India the children were part of a general population surveyed in several villages in the Madanapalle area. The ages of the children ranged from 7 to 14 years, though the groups in Egypt and India included some up to 20.

The results of the pre-vaccination tests are not expressed in terms of the percentage of positive reactors, as is customarily done. Instead, simple histograms are given to describe graphically the frequency distributions of the tranverse diameter of the indurated area of the tuberculin reactions. This form of presentation brings out features which would have been completely obscured by arbitrarily classifying reactions simply as positive or negative. In fact, it provides the basis for a much better understanding of the nature of tuberculin sensitivity.

The four histograms shown in fig. 1 describe the pattern of pre-vaccination tuberculin sensitivity of the children tested with a weak dose of tuberculin in the four countries. General inspection of the histograms discloses one important feature common to all but the one for India: the distributions are clearly divided into two

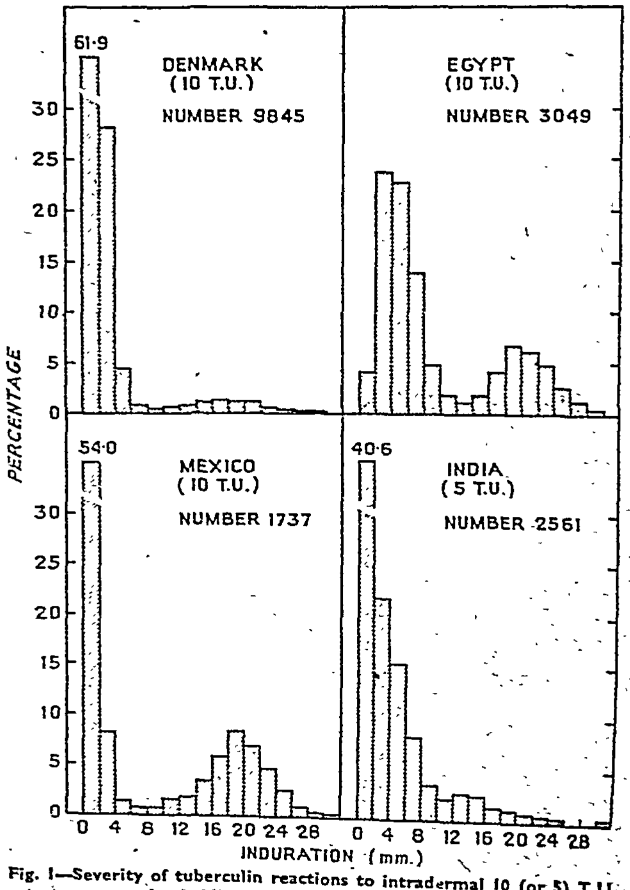

Fig. 1—Severity of tuberculin reactions to intradermal 10 (or 5) T.U. test among school-children in Denmark, Mexico, Egypt, and India.

---

* This is the third of a series of papers entitled Research Contributions of B.C.G. Vaccination Programmes. The first two papers appeared in *Public Health Reports*, 1951, 66, 259, 1427.

† One Tuberculin Unit (1 T.U.) of RT XIX-XX-XXI is prepared to contain 0·00002 mg. in 0·1 ml. of solution.

tuberculosis infection is the only or necessarily the principal cause of tuberculin sensitivity in man Evidence presented here and elsewhere demands, we believe, the recognition of at least two kinds of tuberculin sensitivity. The kind designated here as *high grade sensitivity* (fairly strong reactions to a weak dose of tuberculin, about 5–10 T U) constitutes the specific response to tuberculous infection in the classical sense, as accepted by tuberculosis workers since Koch first discovered that normal animals infected with tubercle bacilli become sensitive to tuberculin The kind designated here as *low-grade sensitivity* (small reactions to a weak dose of tuberculin which appear as large reactions to a strong dose) constitutes a "non specific" response—i e, a response to tuberculin the cause of which is still unknown

According to this interpretation high-grade tuberculin sensitivity should be found wherever human tuberculosis is found, and variations in the proportion of children with this kind of sensitivity ought to correspond roughly to variations in the prevalence of tuberculosis Such was in fact the case in the material presented here Tuberculosis is known to exist in all four localities, and high-grade sensitivity is also found in all four

Moreover, we can accept as an established fact that children are rarely exposed to tuberculosis in Denmark, where the prevalence of the disease is one of the lowest in the world Knowledge of the prevalence of the disease in Mexico and Egypt is much less precise, but it is undoubtedly very much higher than in Denmark As regards the village children tested in India, we know from the results of a careful X ray survey of the general population that only a very low frequency of active cases of tuberculosis was found § From what we know, the prevalence of tuberculosis in each locality corresponds reasonably well to the proportion of children having high-grade tuberculin sensitivity, and these proportions may be estimated from the histograms (cf fig 1) as being roughly 0% in Denmark, 35% in Mexico City and Egypt, and 10% in the village children in South India

The proportion of children having the low-grade kind of tuberculin sensitivity in the four countries corresponds neither with the proportion having high grade sensitivity nor with the prevalence of tuberculosis On purely epidemiological statistical evidence we are forced to postulate that this kind of sensitivity is the result of something other than infection with *Mycobacterium tuberculosis* (of the human or bovine type) We know as yet very little about the cause, but from this and other recently published studies it appears to be related to geographic factors A large and geographically extensive study of tuberculin sensitivity of student nurses in the U.S A has shown the low grade kind of sensitivity to be highly prevalent in the south-eastern states but relatively rare throughout the rest of the country (Palmer et al 1950) In that study, as in the present one, there was a lack of correlation between the prevalence of low-grade sensitivity, on the one hand, and both high grade sensitivity and other signs of tuberculosis, on the other Further, it was pointed out that the low-grade sensitivity is more prevalent in rural than in urban areas while the reverse is true for the high-grade The other study dealing directly with this subject was made in the mountainous area around Darjeeling, north of Calcutta (Bates et al 1951) Children living on tea plantations situated at high altitudes (6000 ft above sea level) had a pattern of tuberculin sensitivity resembling that found in Denmark, children living in the low-lying valleys less than 3 air miles away had a pattern somewhat like that described here for South India So far as was known, the prevalence of tuberculosis was about the same throughout the entire area (Incidentally, it m mentioned that the children in Mexico City l altitude of over 7000 ft) In both the stud United States and the one in Darjeeling the kind of sensitivity was designated as "non spe the hypothesis was offered that it is due to infec an organism antigenically related to *Myco*

Practical Significance

In applying the present results to tuberculo it is of interest to inspect fig 1 a little more note how currently accepted criteria for selecting for vaccination actually operate in different co In most B C G programmes today pre vac Mantoux reactions to a weak dose of tuberc separated at 6 mm (or 5 mm) In Denmark and 6 mm falls at a place on the scale where the reactions is low, with the significant consequen errors in the measurement of reactions will have small effect on the selection of children for vacc We may note, also, that in these countries 8 10 mm would give about the same result In Eg India the frequency of reactions at or near 6 relatively high which means that even small e systematic differences in the measurement of r will make large differences in the proportion of given B C G For example, changing the criter 6 to 10 mm in Egypt means changing the pro vaccinated from 50 to 70%

It is also of interest to consider to what ext proportion of children excluded from vaccinati similar "% positive" figures from tuberculin may be used as valid measures of the frequ tuberculous infection in a population Curves the percentage of "positive reactors" by age in a like Denmark are probably reasonably correct as of tuberculosis infection, because of the relative of low-grade sensitivity But corresponding age in countries where low grade sensitivity is preval be very misleading and subject to even greater both a weak and a strong dose of tuberculin are u the proportion of reactors combined to give "% positive" figure If our hypothesis is confirm low-grade sensitivity is unrelated to tuberculosis in it will be necessary to re-examine the results o tuberculin-testing surveys, since the presence grade sensitivity increases the frequency of the sidered positive reactors in a population It m be that current estimates of the prevalence of tub in many countries have been unduly magnified

Finally, at least on theoretical grounds the and prevalence of low grade sensitivity have im implications as regards B C G vaccination I countries—e g, Denmark—B C G is being given to children who are non sensitive to tuberculin time of vaccination They have neither been pr infected by the tubercle bacillus nor subjected factor that produces the low-grade or non spec of allergy. The B C G -induced allergy later appe these children is therefore uncomplicated by any allergising influences In some other countrie Egypt—B C G is being given mainly to childr already exhibit some sensitivity to tuberculin, bu we have no knowledge of how this complica production and interpretation of B C G -induced

SUMMARY

This paper contains a simple visual analysis patterns of tuberculin sensitivity found before va of children in Denmark, Mexico City, Egypt, an India Histograms of weak dose reactions (5 or on sizable samples of children in these four c bring out the fact that tuberculin sensitivity is separated into three main kinds high-grade se

---

§ Personal communication from Dr Johannes Frimodt Moller, Chief Madanapalle Field Research Station World Health Organization Tuberculosis Research Office and Medical Superintendent Union Mission Tuberculosis Sanatorium, Arogyavaram South India reactions), low-grade sensitivity (small reactions), itive non-sensitivity. The findings are interpreted cating that high-grade sensitivity represents the response to contact and infection with human ulosis in the classical sense. Low-grade sensitivity, other hand, seems to be independent of true ulous infection but closely associated with geo- c factors. The third kind represents children ave neither had a tuberculous infection nor have subjected to the influence of the unknown factor causes low-grade sensitivity. The material shows here are wide variations in different countries in the rtion of children having each of the three different of sensitivity.

e present system of selecting children for vaccination rding to the size of the reaction to a weak dose of rculin) seems to be fairly satisfactory for assuring those with a high level of allergy will not be vacci- d. But it is entirely inadequate for separating children low-grade sensitivity either from those with high- e sensitivity or from those who are non-sensitive to rculin. By the present scheme some children with grade sensitivity are vaccinated and some are not. seems wholly illogical and emphasises the need to y the pattern of tuberculin sensitivity on an inter- onal basis. It also emphasises the unexpected pitfalls n techniques and procedures are directly transplanted 1 one country to another without prior knowledge of differences that may exist in different parts of the ld.

UT, LEUKÆMIA, AND POLYCYTHÆMIA

R. A. HICKLING
B.A., M.D. Camb., F.R.C.P.
PHYSICIAN, CHARING CROSS HOSPITAL, LONDON

OUT occurs very rarely in patients with typical onic myeloid leukæmia and rarely in patients with ical primary polycythæmia; but it does occur not ommonly in patients who have a disorder of the od-forming tissues apparently related both to myeloid æmia and to polycythæmia. In these patients the eloid metaplasia of the spleen and other tissues is posed of cells of the erythroblastic and leucoblastic es, in various proportions and especially of mega- yocytes. The changes in the bone-marrow are either se of hyperplasia involving erythroblasts, leucoblasts, megakaryocytes; or of fibrosis, with various nbers of bone-marrow cells among the fibrous tissue, gakaryocytes being the most conspicuous. Histo- ically, therefore, these cases differ from typical cases myeloid leukæmia in showing myeloid metaplasia olving all bone-marrow elements and not pre- ninantly leucoblastic cells. They are related, histo- ically, more closely to primary polycythæmia, in ich hyperplasia of all bone-marrow elements, in ious proportions, has been recognised for many years eber 1921).

MYELOID LEUKÆMIA

Many workers have stated that gout might be expected occur commonly in cases of chronic myeloid leukæmia, ing to the increased production of uric acid, but that fact it occurs very rarely: a probable case of chronic eloid leukæmia is mentioned in Duckworth's (1889) atise on gout; Roberts and Rose Bradford (1907) only 1 case of gout and myeloid leukæmia, and in at the patient had had gout for many years before the leen became enlarged and the blood leukæmic; and Wintrobe's (1951) textbook only one reference to gout and leukæmia is given, and that is to an atypical case of leukæmia (Brunner 1932). Forkner (1938) says that the simultaneous occurrence of gout and leukæmia is so rare that any real relationship seems doubtful. In a recently published case attacks of gout occurred soon after the beginning of a course of X-ray treatment in a patient with typical chronic myeloid leukæmia (Shorvon 1946).

POLYCYTHÆMIA

Gout occurs in a small proportion of patients with polycythæmia. Of 168 cases of polycythæmia reviewed by Tinney et al. (1945), gout occurred in 8, and of 125 cases of polycythæmia reviewed by Videbæk (1950) gout occurred in 11. In 8 cases gout began from two months to three years before polycythæmia was recognised (Weber 1921, 1934, Rosenthal and Bassen 1938, Tinney et al. 1945), and in 7 cases gout began from three months to four years after polycythæmia was recognised (Weber 1921, Avery 1930, Rosenthal and Bassen 1938, Reifenstein 1939, 1945, Tinney et al. 1945).

It is known that in some patients with polycythæmia who survive many years the disorder gradually changes, the polycythæmia diminishing, the spleen enlarging, and increased leucoblastic and megakaryocytic hyperplasia of the spleen and other tissues developing, with increased leucocytosis and with immature leucocytes in the circulating blood (Rosenthal and Bassen 1938, Stone and Woodman 1938, Tinney et al. 1945, Videbæk 1945).

When polycythæmia is seen at that stage, a fairly characteristic picture is presented. The patient is elderly and complains of abdominal pain, discomfort, or swelling due to the large spleen; of hæmorrhages into the tissues or from the alimentary tract; of tiredness and weakness; and of cramps in the legs at night. The patient may have had attacks of gout, or may have chronic gout. There may be acne rosacea, a slightly yellowish complexion, no enlarged lymphatic glands, a large hard spleen, and a large soft liver. Examination of the blood shows a slight anæmia, a moderate leucocytosis, and a few immature leucocytes and nucleated red cells. Examination of the bone-marrow shows either large numbers of megakaryocytes in an active marrow or sclerosis of the marrow, often with megakaryocytes among the fibrous tissue.

In some patients who present these features no history suggesting preceding polycythæmia can be obtained, though "chlorotic polycythæmia" (Rosenthal and Bassen 1938) could not be recognised from the history. When there is no evidence of preceding polycythæmia, "megakaryocytic myelosis" or "myelosclerosis" may be diagnosed, but many different names have been used to describe such cases, and there is disagreement about the nature of the disorder and its relationship to chronic myeloid leukæmia. Gout may precede the finding of the enlarged spleen and other features, or may occur while the patient is under observation. For example, in 6 cases gout occurred from seven to thirty-two years before recognition of the disorder of the blood-forming tissues (Hagedorn 1926, Hoffmann 1926, Coste et al. 1948, Merskey 1949), and in 1 case five years after the disorder was recognised (Brunner 1932). Of 30 patients with "chronic marrow failure, myelosclerosis, and extra-medullary hæmatopoiesis" 2 had gout (Wyatt and Sommers 1950).

I have had under my care 9 patients with gout, splenomegaly, and immature cells in the circulating blood; 5 of these had polycythæmia at some stage of the disorder, but in the other 4 there was no history suggesting preceding polycythæmia, nor did this develop under observation.

The presenting symptoms which led to the discovery of splenomegaly and the other features were abdominal pains or discomfort in 3 cases, hæmorrhage per rectum in 2, diarrhœa and hæmorrhage per rectum in 1, epistaxis in 1, weakness and tiredness in 1, and gout in 1.

Of these 9 patients 4 had gout before any other symptoms of the disorder of the blood-forming system , attacks of gout began one, three, eight, and forty-one years before the splenomegaly was discovered The 5 other patients began to have attacks of gout one, two, four, five, and eleven years after splenomegaly was discovered

These 9 patients were observed for from four years and four months to seventeen years, 7 having been observed for more than six years Three patients developed *chronic gout, and this was their chief disability* towards the end of their lives Six patients had courses of X-ray treatment to the enlarged spleen, which in 4 produced considerable improvement in the patient's feeling of well-being and decreased the size of the spleen Courses subsequent to the first had diminishingly favourable effects In 1 patient an attack of gout was precipitated by each course of treatment

Severe anæmia occurred as a terminal event, with cachexia, in 2 patients Otherwise severe anæmia occurred only after intestinal hæmorrhages, and in 1 patient for a short time without evident cause, recovery taking place later

Of the 5 patients who had polycythæmia 2 had it when first seen, one for abnormal tiredness, and the other for a hæmorrhage per rectum The 3 other patients developed polycythæmia under observation, either spontaneously or as an effect of treatment with iron, liver extract, or X-ray treatment to the enlarged spleen In all 5 patients polycythæmia disappeared later

Necropsies were made of 8 of the 9 patients who had gout In 6 of these the bone-marrow was hyperplastic, megakaryocytes were the predominant cells, and there was no sign of sclerosis In 1 patient the bone-marrow was sclerotic, but large numbers of megakaryocytes were present in the fibrous tissue, and in the remaining patient the bone-marrow was sclerotic, without megakaryocytic activity, though megakaryocytes were prominent in the myeloid metaplasia of the spleen

Case 1 —A man, aged 71, died in March, 1945, of cachexia and chronic gout, after seven years' observation The presenting symptom, gout, had been present in attacks since 1897 When he was first seen for gout in 1938, a large spleen was found There was no anæmia, there had been no polycythæmia, and there was moderate leucocytosis, about 25,000 per c mm , with a few immature leucocytes Severe anæmia developed at the end of 1938, and by the middle of 1939 the patient was polycythæmic He had moderate anæmia and abnormal bruising from then till death His blood uric acid level was constantly above 7 mg per 100 ml in 1938–45 He became bedridden from chronic gout in 1944

Necropsy showed bone marrow hyperplastic, megakaryocytes very numerous, no fibrosis, spleen affected with myeloid metaplasia and fibrosis, with malpighian bodies preserved in some sections and absent in others and the liver with slight myeloid metaplasia

Case 2 —A man, aged 66, died in June, 1947, of congestive heart failure, after six years' observation The presenting symptoms were weakness and tiredness in 1941, and a large spleen and polycythæmia were found Gout began in 1938, and chronic gout developed in the last four years of life The patient had never had severe anæmia, but he had polycythæmia in 1941 and 1945, with leucocytes normal or slightly increased immature leucocytes being constantly present in very small numbers His serum uric acid level was 6 8–12 9 mg per 100 ml *in 1944–47 X ray treatment in* 1944 and 1946 had little effect on the size of the spleen

Necropsy showed bone marrow hyperplastic, with very large numbers of megakaryocytes and no fibrosis , the spleen with slight myeloid metaplasia , liver with cirrhosis and no myeloid metaplasia and small areas of myeloid metaplasia in the kidneys

Case 3 —A man, aged 49, died in June, 1945, of weakness, wasting, and anæmia, after six and a half years' observation The presenting symptom was abdominal discomfort due to a large spleen in January, 1939 The patient had had attacks of gout in the feet since 1931 , these recurred often, and chronic gout developed towards the end of his life He had never had polycythæmia He had slight anæmia at first leucocytosis (38,000 per c mm) with a few immature , and nucleated red cells constantly This leucocytosis d appeared under X ray treatment In 1943 and 1944 th number of nucleated red cells greatly increased and surpass the leucocytes in number The serum uric acid level w constantly high, above 7 0 mg per 100 ml in 1939–45

Necropsy showed bone marrow replaced by fine fibro tissue containing endothelial lined spaces packed with myelo cells with large numbers of megakaryocytes , the spleen wit intense myeloid metaplasia, large numbers of megakaryocyt and some *increased fibrosis , and intense myeloid* metapla of the liver

Case 4 —A man, aged 61, died in April, 1945, of weakne and wasting, after nine years' observation The presentin symptom was hæmorrhage per rectum in November, 193 *when a large spleen was found Attacks of gout began* i 1929 The first hæmorrhage per rectum took place in 1930 when the patient was found to be plethoric, but his sple was not felt at that time He was subject to abnorm bruising from 1930 to his death He had never had seve anæmia , the polycythæmia disappeared in 1941 and nev reappeared Moderate leucocytosis was present, nev exceeding 15,000 per c mm , and there were a few immatur leucocytes, never exceeding 3% Four courses of X ra treatment were given—one in 1938, two in 1939, and one i 1940, the first two courses producing considerable improvemen in health

Necropsy showed bone marrow hyperplastic, with ve large numbers of megakaryocytes and some slight fibrosis the spleen with fibrosis, myeloid metaplasia, and very fe and small malpighian bodies , and the liver with no myeloi *metaplasia*

Case 5 —A man, aged 58, died in February, 1950, o cachexia, anæmia, and heart failure, after seventeen years observation The presenting symptom was abdominal pain since 1920, later found to be due to repeated hæmorrhages into th *perinephric tissues, producing a large hæmatoma, which was* opened in 1933 The patient had a large spleen and a large liver, slight anæmia, and leucocytosis of 20,000–38,000 per c mm in 1933–40 Leucopenia followed X ray treatment in 1940, 1941, and 1942 The patient had never had polycythæmia or any past history suggesting this A few immature leucocytes (2–4%), and a few nucleated red cells were alwa found The patient had gout in his great toes in 1944 and 1947 His blood uric acid level was constantly high in 1930–50, being nearly always above 7 mg per 100 ml

Necropsy showed bone marrow active with very numerous *megakaryocytes and slight fibrosis , the spleen with localised* areas of myeloid tissue with large numbers of megakaryocyt and some generalised myeloid metaplasia, but with malpighia bodies preserved , and the liver with very slight myeloid metaplasia

Case 6 —A *woman, aged 63, died in March, 1936, after* a operation for ligature of the splenic vessels, after five an a half years' observation The presenting symptom wa epistaxis in 1930, when a large spleen was found The patie had been subject to abnormal bruising since 1920, and achi in the left side of her abdomen since 1923 She had attacks gout in her hands and feet in 1934–36, and moderate anæm in 1930–36, never polycythæmia, and moderate leucocyto usually about 20,000 per c mm , with a few immature leucocytes, never exceeding 3% Her blood uric acid level 12 5–16 0 mg per 100 ml in 1936

Necropsy showed bone marrow hyperplastic with very lar numbers of megakaryocytes and no fibrosis , the spleen wi intense myeloid metaplasia with large numbers of me karyocytes and no malpighian bodies and the liver wi moderately intense myeloid metaplasia with large numb of megakaryocytes

Case 7 —A man, aged 63 died in June, 1942, after a operation for ligature of the splenic vessels, after six and a half years' observation The presenting symptom was pa in the left side of his abdomen in 1936, when a large sple was found The patient was subject to abnormal bruis from 1935 to his death He had repeated hæmorrhages in his gastro intestinal tract from 1939 to his death He had attacks of gout in his great toes in 1940–42 His blo uric acid level was 6 5–8 0 mg per 100 ml in 1939–42 He had moderate polycythæmia at times, anæmia after th *severe gastro intestinal hæmorrhages, and moderate* leu cytosis, 20,000–30,000 per c mm , a few immature leucocyte from the occluded hepatic-vein pressure to obtain the effective portal-vein pressure.

These theoretical considerations do not detract from the practical value of the method for assessing portal hypertension. It is a useful preliminary to vascular surgery in cirrhosis both to confirm the diagnosis of portal venous hypertension and to distinguish the site of the portal venous obstruction. It may also be useful, after portacaval anastomosis for cirrhosis, to repeat hepatic-vein catheterisation; a continued low pressure reading confirms that the shunt is still patent.

SUMMARY

The pressure obtained with a catheter occluding a hepatic vein does not differ significantly from that obtained directly from a portal-vein radicle, unless there is extrahepatic portal venous obstruction.

The mean occluded hepatic venous pressure in 24 patients without liver disease was 6·8 mm. Hg. In 11 patients with portal cirrhosis the mean pressure was 22·0 mm. Hg. Raised values were also obtained in 2 patients with subacute hepatitis and in four patients with congestive heart-failure. Normal values were found in 3 patients with extrahepatic portal venous hypertension and in 12 patients with obstructive jaundice (9 extrahepatic and 3 intrahepatic).

Theoretical objections to the method do not invalidate its use in the clinical assessment of portal hypertension.

We are indebted to Mr. Sol Cohen for kindly referring one patient; to our surgical colleagues for their coöperation: and to the Lund Fund of the Diabetic Association for an expenses grant.

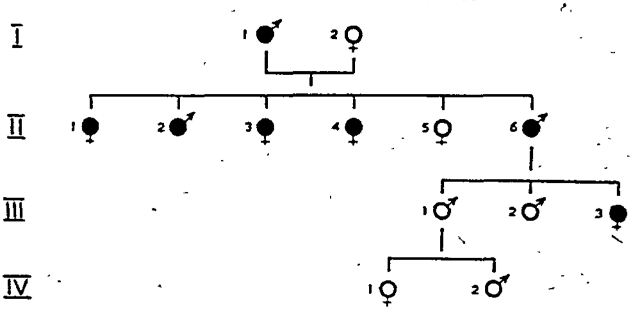
ADDENBROOKE'S HOSPITAL, CAMBRIDGE

HEREDITARY spastic paraplegia is a well recognised though rare disorder. Few affected families have been described in this country, until recently, apart from those recorded by Gee (1889), Holmes (1905), and Ogilvie (1908). In America Rhein (1916) published an extensive review of the subject, as did Paskind and Stone (1933), the latter with a necropsy report. Bell and Carmichael (1939) were only able to find one family with this disease in the previous twenty-five years' records of the two major hospitals for nervous diseases in London, and their comprehensive review, concerned chiefly with the genetic aspects, is based largely on families recorded in the Continental literature. Garland and Astley (1950) report a further family, and Bickerstaff (1950) records the largest number of cases so far found in one family in this country.



Family with hereditary spastic paraplegia: affected members shown in black. No known consanguinity in marriages.

The criteria of differentiation of this condition from other heredofamilial disorders of the nervous system, such as the hereditary ataxias and hereditary ataxia with paraplegia, are usually accepted as being the absence of ataxia and of cerebellar signs other than nystagmus. Whether any genetic relationship exists between spastic paraplegia and the hereditary ataxias is uncertain, but examples of hereditary spastic paraplegia occurring in the same stock as the hereditary ataxias have not been observed (Bell and Carmichael 1939). The post-mortem findings in these diseases are so diverse, and often apparently lacking in correlation with the previous clinical manifestations, that they do not provide a firm basis on which to form a classification in our present state of knowledge.

The essential features of hereditary spastic paraplegia are increasing spasticity of the lower limbs with relatively little loss of power, often associated with nocturnal flexion spasms of the feet, the upper limbs being slightly or not at all affected. The symptoms tend to appear at the same age in a particular family in which several members are affected in one or more generations, a fact which has been emphasised by Garland and Astley (1950). Various associated abnormalities have been described in some families; these include pes cavus reducible on standing (Bickerstaff 1950), amyotrophy, mental deterioration, speech disturbances, optic atrophy, and extrapyramidal lesions.

PRESENT FAMILY

The present family, inhabitants for several generations of a village adjacent to the Cambridgeshire Fens, is described partly because of the rarity of the condition in this country, and partly because of the presence in several members of extrapyramidal disorders, an association which has not been noted in any of the families so far reported in this country.

The pedigree is shown in the accompanying diagram. Nos. II 2, II 4, II 5, II 6, III 1, III 2, and III 3 have been examined. Information about the other members of the family has been derived from questioning all the members interviewed. The father of I 1 was a strong active man who lived to an old age and, so far as is known, had no disability. His wife was also healthy.

I 1.—Male. Died at 74. Said to have had a slight tremor of the right arm and of the toes of both feet, coming on when he was a young man. During middle age, soon after dislocating a shoulder, he developed difficulty in walking and a tendency to a shuffling gait. Disabilities were insufficient to prevent his working as a farm labourer.

I 2.—Wife of I 1. Said to be healthy and died aged 75.

II 1.—Female. Severely crippled; never able to walk, owing to paralysis of legs and arms. Died at 20. Said to have had "cancer on the chest."

II 2.—Male, aged 65. At age of 10 progressive weakness of the left leg, with foot-drop, gradually came on. At 20 he noticed slight weakness of the right leg, and both legs tended to shake, especially when he was tired. Contractures had developed in the left leg, and permanent foot-drop necessitated a surgical boot. At 30 uncontrollable movements of head, arms, and legs, worse when he was unoccupied, came on gradually. Weakness of his legs progressed very slowly and insidiously, with increasing contractures in the legs, particularly the left. He could get about with difficulty, using crutches, until the age of 60, when he had to give up work, having hitherto run a small shop. Since his retirement his difficulty in walking has steadily increased, and he is now

TABLE II—SERUM CHLORAMPHENICOL LEVELS AFTER RECTAL ADMINISTRATION OF 17 MG PER KG BODY-WEIGHT

Case no	Serum-chloramphenicol (µg per ml)				
	1st hour	2nd hour	4th hour	8th hour	12th hour
1			20	20	20
2	40	20	20	—	—
3	40	20	20	40	30
Mean	40	20	20	20	17

= No sample available — = Non inhibitory concentrations

When a dose of 17 mg per kg was given per rectum, the antibiotic serum level behaved in a similar way, but the concentration at a given time was always less than with the bigger dose (table II and the figure)

On a previous occasion, I estimated the serum-chloramphenicol in a few patients after oral doses of 50 and of 25 mg per kg (El Borolossy 1951) The figure compares the levels recorded then with those now obtained after rectal administration It will be seen that, with a dose of 25 mg per kg given by rectum, the serum-chloramphenicol attains a high level rapidly, and then declines rapidly during the second to the fourth hours When the same dose is given by mouth, the serum level rises slowly to reach its maximum at the fourth hour Between the fourth and the twelfth hours the two curves lie close to one another A possible explanation of the differences in absorption during the first four hours is that when given by rectum the antibiotic is immediately brought into contact with an absorbing surface, whereas when it is given by mouth it has to pass the stomach barrier before reaching the absorbing surface of the intestines It should, however, be noted that all the serum levels obtained, whether administration was oral or rectal, were above that required for inhibition of the majority of sensitive bacterial strains

CONCLUSIONS

Rectal administration of chloramphenicol in doses of 17 mg, or more, per kg body-weight produces an effective concentration of the antibiotic in the blood for the following twelve hours Given per rectum a dosage of 17–25 mg per kg should be adequate in the treatment of most cases of typhoid fever

Addendum —After this investigation was completed I received a letter from Dr P Moggi of Milan indicating that "the hæmatic concentration of chloramphenicol given per rectum is nearly equivalent to that obtained when this antibiotic is administered per os "

Preliminary Communication

DERIVATIVE OF p-AMINOSALICYLIC ACID WITH ENHANCED ANTITUBERCULOUS ACTIVITY

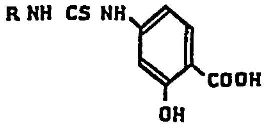
The many attempts that have been made to prepare derivatives of p aminosalicylic acid with enhanced antituberculous activity have so far failed in their object, all alterations in chemical structure so far tried having resulted in products of unaltered or diminished activity with the possible exception of the synthesis of the phenyl ester[1] The present work represents a new line of attack on this problem, of which the preliminary results appear to offer some promise

The powerful antituberculous activity of derivatives of p aminobenzaldehyde thiosemicarbazone, discovered by Domagk and his collaborators,[2] is well known, and it has also been found that considerable variations in this activity result from altering the substituents in the amino group In addition, it has been found in this institute[3] that some in-vitro antituberculous activity is exhibited by certain cyclic compounds (thiouracil derivatives) which contain the thiocarbamido grouping The object of our experiments was to explore the possibility of obtaining enhanced antituberculous activity by combining thiocarbamido and/or p-aminobenzaldehyde thiosemicarbazone groupings with p aminosalicylic acid in one molecule

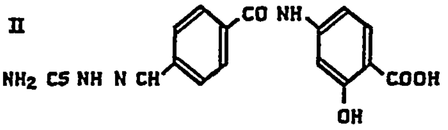
With this purpose in mind the following four types of compound have been synthesised (*a*) 4-thiocarbamido derivatives of salicylic acid (I, R = H, Me, *n*-Pr, Ph), (*b*) the thiosemicarbazone of 4-(4′ aldehydo)benzamidosalicylic acid (II), (*c*) the thiosemicarbazone of 4-(4′-aldehydo)phenylcarbamidosalicylic acid (III), and (*d*) the thiosemicarbazone of 4 (4′-aldehydo)phenylthiocarbamidosalicylic acid (IV)

The results of in-vitro biological tests are shown in the accompanying table It will be seen (table, A) that with a small inoculum and prolonged incubation compound IV is rather less active than p aminosalicylic acid, whilst the other compounds are all much less active It was observed, however, that compound IV was somewhat unstable in solution, and the tests were therefore repeated with a larger inoculum and shorter period of incubation, under these conditions (table, B) compound IV is considerably more active than p-aminosalicylic acid

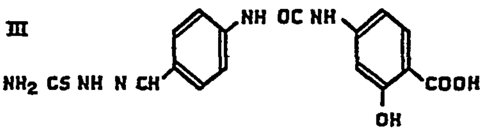
I



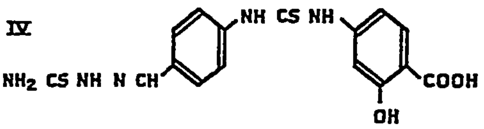
II



III



IV



This observation made it desirable to carry out an in-vivo test of the antituberculous activity of compound IV Mice were injected intravenously with 0 1 mg (moist weight) *Mycobacterium tuberculosis*, strain H37RV, and compound IV was administered at 0 5% in the diet (approx 30 mg daily) for 28 days from the day of infection No toxic effects were observed, and the median survival-time of the treated mice was 30 days as compared with 21 days for an untreated control group

Compound IV is more active in vivo than p aminosalicylic acid but less so than streptomycin, assessed by similar chemotherapeutic tests in mice, its activity is probably more of the order of the thiosemicarbazones The sharpness of the end-point obtained with compound

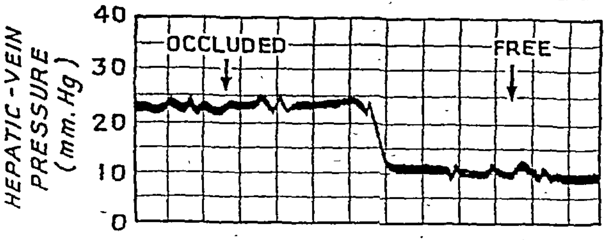

Fig. 3—Fall in pressure as catheter is withdrawn from occluded to free hepatic vein in portal cirrhosis (case 1).

hypertension. This is an interesting finding in view of the reported development of intrahepatic portal hypertension in such patients (Ahrens et al. 1950).

Infective Hepatitis

The mean occluded hepatic-vein pressure was normal in the 4 patients in this group, though 2 had pressures outside the upper range of normal. These 2 patients both had subacute hepatitis, and it seems possible that they already had some distortion of lobules, fibrosis, and portal venous obstruction. The finding of normal pressures in the acute stage of infective hepatitis suggests that the splenomegaly which may accompany this disease is not due to portal hypertension.

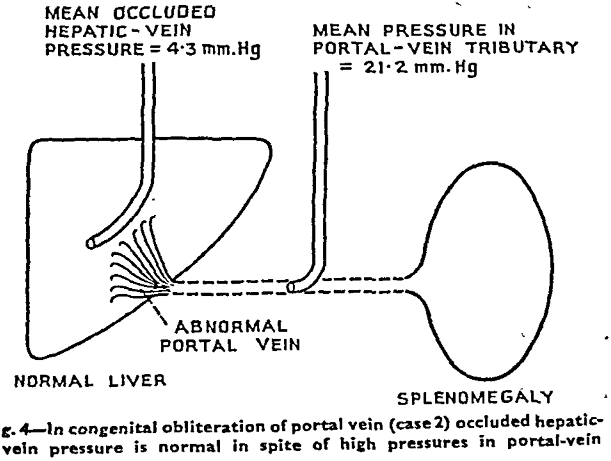
Congestive Cardiac Failure

The occluded hepatic-vein pressure in 2 patients with congestive heart-failure due to rheumatism and in 2 with cor pulmonale was raised, and there was only a slight gradient between the occluded and the free pressures (table III). This reflects the rise in pressure in the right side of the heart. The finding of a high occluded hepatic-vein pressure can result from long-continued congestive heart-failure.

Case 5.—A housewife, aged 41, with cor pulmonale, had had asthma since adolescence, and in the last year had developed increasing dyspnœa, œdema of the ankles, and swelling of the abdomen. On admission she showed the classical features of severe cor pulmonale, and the spleen was found to be enlarged. The occluded hepatic-vein pressure was 21·7 mm. Hg, and the free pressure 21·4 mm. Hg.

DISCUSSION

The present results are in agreement with those of Myers and Taylor (1951) using the same technique in normal and cirrhotic persons. Values in the same range are recorded directly in the portal vein exposed at operation (Walker 1952, Blakemore 1952). Pressures taken from fine plastic tubes inserted into a portal-vein radicle at operation also agree well with the occluded hepatic-vein pressures (table I). The findings of Myers and Taylor (1951) and Friedman and Weiner (1951) in laboratory animals are further confirmatory evidence. It therefore seems probable that the pressure measured in an occluded hepatic vein indicates the height of the portal venous pressure, although it is difficult to provide a satisfactory theoretical basis for this assumption.



MEAN OCCLUDED HEPATIC-VEIN PRESSURE = 4·3 mm.Hg
MEAN PRESSURE IN PORTAL-VEIN TRIBUTARY = 21·2 mm.Hg
ABNORMAL PORTAL VEIN
NORMAL LIVER
SPLENOMEGALY

Fig. 4—In congenital obliteration of portal vein (case 2) occluded hepatic-vein pressure is normal in spite of high pressures in portal-vein tributary.

A pressure gradient exists from the portal vein to the hepatic veins. This pressure head is dissipated in the hepatic sinusoidal bed in overcoming vascular resistance. The occluding catheter stops blood-flow through a hepatic-vein radicle and the portal-hepatic vein pressure gradient in that radicle is lost. The static column of blood built up in this way is a measure of the pressure in the hepatic sinusoidal bed. It may in fact be more correct to call the pressure measured by the occluding catheter the intrasinusoidal pressure rather than the portal venous pressure. The intrasinusoidal pressure may be produced not only by the portal vein but also by the hepatic arterioles which open into the sinusoids. The agreement between values for portal venous pressure and the occluded hepatic-vein pressure suggests that the hepatic arterial component must play little part in the genesis of the intrasinusoidal pressure in normal man. This may not be true in hepatic cirrhosis, where direct portal venous-hepatic arterial shunts have been postulated (Herrick 1907, Epplen 1922, Dock 1942), though not universally accepted (Wilson 1951, Popper et al. 1952). It is unfortunate that it has not been possible to compare simultaneously the pressures in the occluded hepatic vein and those in the portal vein, but in one patient the pressure taken from an abdominal portal collateral was within 1 mm. Hg of that obtained simultaneously from the occluded hepatic vein. Direct shunting of arterial blood at high pressure into the portal vein in cirrhosis seems unlikely. Shunts between the hepatic artery and the hepatic veins in cirrhosis might cause a rise in hepatic venous pressure without there necessarily being a rise in portal-vein pressure. However, the oxygen unsaturation of the hepatic-vein blood did not differ from that in patients without liver disease. Shunts of any magnitude between hepatic artery and hepatic veins do not seem likely in cirrhosis, and intrahepatic shunting of blood therefore does not interfere with the practical application of this technique in normal subjects or in cirrhosis.

TABLE III—SUMMARY OF RESULTS

Type of case	No. of cases	Mean hepatic-vein pressures (mm. Hg)	
		Occluded	Free
Without liver disease ..	24	6·8 ±0·49† (2·6 – 11·2)‡	4·9 ±0·46 (0·6 – 10·6)
Portal cirrhosis *	11	22·0 ±1·94 (15·6 – 35·2)	8·9 ±1·02 (3·9 – 15·6)
Extrahepatic portal hypertension	3	8·0	5·2
Obstructive jaundice:			
Extrahepatic	9	6·7 ±1·32 (0·9 – 12·3)	3·4 ±1·16 (–2·5 – +8·8)
Intrahepatic	3	9·6	6·7
Infective hepatitis	4	10·5	5·8
Congestive heart-failure ..	4	13·5	13·2

* Includes one patient with hæmochromatosis.
† Standard error of the mean.
‡ Range.

Differences in the position of the catheter tip produce slight and insignificant changes in the occluded hepatic-vein pressure. There is always a small fluctuation in pressure with the phases of respiration, and the height of the pressure varies somewhat with the type of respiration. Forced inspiration causes a marked rise in pressure. A rise in intra-abdominal pressure, due for example to ascites or to gaseous distension, will produce a conspicuous increase in intrahepatic vascular pressures. This will be reflected in both occluded and free hepatic-vein pressure and may be responsible for the higher mean free hepatic-vein pressure in the cirrhotic group. If abdominal distension from any cause is present, the intra-abdominal pressure must be measured and subtracted

RESULTS OF IN-VITRO TESTS

—	Compound	Inhibitory concentration * (mg per 100 ml)
		14 days incubation inoculum 0 0008 mg per ml †
A	I (R = H)	10 0
	II	2 5
	III	2 5
	IV	0 625
	P A S (Na salt)	0 156
		7 days' incubation, inoculum 0 008 mg per ml †
B	I	10 0
	II	10 0
	III	2 5
	IV	0 625
	P A S (Na salt)	> 20 0

* In a synthetic medium containing albumin 0 25 %
† Moist weight, *Myco tuberculosis*, strain H37RV

IV in the in-vitro tests, and its relative independence of inoculum size, also suggest a similarity in action to the thiosemicarbazones rather than to *p* aminosalicylic acid On the other hand, the tolerance of the mice in the above-described experiment to large doses of the compound indicates that its toxicity is lower than that of the thiosemicarbazones

More detailed pharmacological and chemotherapeutic studies of compound IV are now in progress

It is of interest that since the chemical part of this work was completed, two papers [4 5] have appeared dealing with the preparation of *p*-thiocarbamido derivatives of salicylic acid (cf series I above), the authors of these papers agree with our conclusion that this series shows no enhancement of antituberculous activity as compared with *p* aminosalicylic acid

Unusual Manifestations of Bronchial Carcinoma

THE section of medicine of the society met on April 28, under the chairmanship of Sir ALUN ROWLANDS, president of the section, to discuss Unusual Manifestations of Bronchial Carcinoma

Dr PHILIP ELLMAN reviewed the common manifestations of bronchial carcinoma, a disease that caused more deaths in 1951 than respiratory tuberculosis More cases were now being discovered by means of miniature fluorography in the silent stage when the chances of successful surgical treatment were greatest He described 6 examples of joint manifestations, in some of which the joint changes preceded the symptoms directly due to the lung lesion The patients had polyarthritis of rheumatoid type or pulmonary osteoarthropathy with gross clubbing of the fingers and toes and enlargement of the nose The most striking and important feature was the very rapid reversal of the condition after pulmonary resection, dramatic improvement sometimes being noticed within a few hours of operation The conjunction of bronchial carcinoma and pulmonary tuberculosis was not very rare now that carcinoma had become so common and the prevalence of tuberculosis in middle-aged men had risen Certain pneumoconioses, especially asbestosis, were sometimes associated with carcinoma and it was possible that there was a causal relationship He described a patient with generalised "honeycomb lungs" and bronchial carcinoma, it was suggested that the prolonged inhalation of chrome dust might have produced both conditions Dr Ellman referred to carcinoma of the lung presenting as a general medical disorder—e g, "pyrexia of unknown origin," influenza, cardiac conditions, Addison's disease, abdominal conditions, and low back pain

Mr T HOLMES SELLORS said that it was impossible to estimate what proportion of patients had operable tumours when diagnosed, it was probably of the order of 15% Although routine radiography did bring to light some truly symptomless cases, this was less common than many believed, patients hid their symptoms and preferred to visit a mass miniature radiography unit rather than admit their ailments to their doctors Of 200 consecutive cases at Harefield Hospital, 67% presented with respiratory symptoms, 11% with general symptoms, and the remainder with symptoms directing attention to other systems General constitutional symptoms might predominate and the clinical picture might be one of "pyrexia of unknown origin" or unexplained loss of weight The first symptoms and signs might be due to metastases in the cervical nodes, skin, adrenals, liver, or bone, and a particularly misleading symptom was persistent back pain On occasion this had been wrongly diagnosed and treated by manipulation A very difficult manifestation in the nervous system was vague personality changes due to metastases in the frontal lobe He had seen intussusception due to secondaries in the small intestine that were only discovered after operation The diagnosis of unresolved pneumonia could be the cause of unnecessary delay, and the term should be abolished. Mr Holmes Sellors emphasised the need to investigate fully all cases of repeated bloodstaining of the sputum Pleural involvement by the tumour might lead to referred pain in the abdomen Mediastinal involvement might cause loss of voice, dysphagia, or obstruction of the superior vena cava The deep chest pain that was so common a complaint might also arise from invasion of mediastinal structures Among the cardiac manifestations were heart block, pericarditis, and auricular fibrillation

Dr R A HENSON discussed the neurological manifestations of bronchial carcinoma and described 15 cases seen at the London Hospital In none of them was there evidence of metastases in the nervous system Subacute cerebellar degeneration, sensory neuropathy—and polyneuritis had already been described, and he gave 8 examples of motor neuropathy, a condition not previously recorded in this disease In 7 the nervous symptoms preceded those directly due to the carcinoma, and in 1 they began nine months after an apparently successful pneumonectomy All these patients had an atrophic paresis, limited at first to the limb girdles In some there was also bulbar palsy, ptosis, diplopia, and depression or absence of the tendon reflexes Only 1 had any sensory loss, although 6 had paræsthesiæ and pain, sometimes very severe 4 had extensor plantar responses and 1 had cerebellar signs In 1 there were no abnormal signs in the nervous system, the condition appearing as a pure myopathy Some degree of myopathy may have been present in all the cases In 1 there was a remission after pneumonectomy, and another patient improved after neostigmine had been given because of an erroneous diagnosis of myasthenia gravis, but 2 others had similar remissions although they received no treatment at all 1 had a remission after multiple vitamin therapy, but it was unlikely that the treatment was responsible The cause of the lesions in the nervous system was unknown It had been suggested that they were due to metabolic disorders or to a virus infection In 2 of Dr. Henson's cases, the post-mortem changes in the spinal cord were apparently inflammatory It was probable that the cancer and the neuropathy were linked by a common cause, rather than that one was directly caused by the other

[5] Tietze, E, *Petersen* S Domagk, G *Ibid*, 1953 86 312

from the occluded hepatic-vein pressure to obtain the effective portal-vein pressure.

These theoretical considerations do not detract from the practical value of the method for assessing portal hypertension. It is a useful preliminary to vascular surgery in cirrhosis both to confirm the diagnosis of portal venous hypertension and to distinguish the site of the portal venous obstruction. It may also be useful, after portacaval anastomosis for cirrhosis, to repeat hepatic-vein catheterisation; a continued low pressure reading confirms that the shunt is still patent.

SUMMARY

The pressure obtained with a catheter occluding a hepatic vein does not differ significantly from that obtained directly from a portal-vein radicle, unless there is extrahepatic portal venous obstruction.

The mean occluded hepatic venous pressure in 24 patients without liver disease was 6·8 mm. Hg. In 11 patients with portal cirrhosis the mean pressure was 22·0 mm. Hg. Raised values were also obtained in 2 patients with subacute hepatitis and in four patients with congestive heart-failure. Normal values were found in 3 patients with extrahepatic portal venous hypertension and in 12 patients with obstructive jaundice (9 extrahepatic and 3 intrahepatic).

Theoretical objections to the method do not invalidate its use in the clinical assessment of portal hypertension.

We are indebted to Mr. Sol Cohen for kindly referring one patient; to our surgical colleagues for their coöperation; and to the Lund Fund of the Diabetic Association for an expenses grant.

Since his retirement his difficulty in walking has steadily increased, and he is now

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

THE society's 73rd annual congress was held in London, under the presidency of Mr ALEXANDER MACRAE (Newcastle) on April 23–25 Over 200 members were present

After a short opening speech by the PRESIDENT on Prognosis in Malignant Melanoma of Choroid and Ciliary Body, in which he reviewed the progress of over 60 consecutive cases papers were read on an interesting diversity of subjects Mr E F KING reported 2 cases of thyrotoxicosis after keratoconus and discussed the significance of their association Mr P L BLAXTER described and discussed a new provocative test for glaucoma (the bulbar pressure test) Mr A G CROSS gave a humane account of the liberal ideal in the exercise of ophthalmology Mr ARTHUR LISTER and Mr F B ZWINK followed the course of central retinal vein thrombosis with different treatments concluding that no essential benefit accrued from these Mr FREDERICK RIDLEY surveyed 600 contact-lens cases treated at the Westminster branch of the Moorfields, Westminster and Central Eye Hospital Mr T KEITH LYLE discussed some pitfalls in the diagnosis of plerocephalic œdema Mr A L MCCURRY reported some cases of the Stevens-Johnson syndrome, and Mr J H DOGGART gave an engaging account of the occasions in which calcium is deposited in the cornea

The Bowman lecture was delivered by Sir GEOFFREY JEFFERSON, F.R.S, who spoke on the Syndromes of the Cavernous Sinus

Chemotherapeutic Agents in Opthalmology

Opening the main discussion, Prof ROBERT CRUICKSHANK emphasised that the variations in the sensitivity of bacteria, and the possibility of otherwise sensitive-organisms developing resistant variants, made it essential that antibiotics should be used for the treatment of specific infections and not of clinical syndromes If this was to be done there must be close collaboration between clinician and bacteriologist It was essential never to forget possible toxic manifestations of antibiotics and chemotherapeutic agents allergic reactions, blood dyscrasias, and secondary effects resulting from elimination of normal flora were among the most important Local irritation or necrotic action was especially important in ophthalmology, and might be assessed by the effect of antibiotics on tissue culture Drug resistance might sometimes be overcome or prevented by the combination of two chemotherapeutic agents, and synergistic effect might be obtained by combining two bactericidal substances There was a possibility, however, of antagonistic action when a bactericidal drug was used in combination with a bacteriostatic substance

Prof ARNOLD SORSBY pointed out that the eye was pharmacologically a double organ Diseases of the external eye responded to antibiotics in the same way as diseases of other tissues of the body However, drugs given systemically were prevented by the blood-aqueous barrier from entering the intra ocular fluids and cornea freely Consequently the treatment of infections of the interior of the globe and cornea involved special problems Small concentrations of antibiotics could be found in the aqueous after enormous systemic doses, but only penicillin was sufficiently non-toxic to allow such dosage Subconjunctival injection was required if high intra ocular concentration was to be obtained Antibiotics suitable for this method of administration were penicillin and streptomycin in solution, and chloramphenicol in micronised suspension Of the relatively non toxic members of the sulphonamides, sulphamerazine was the most likely to be effective in intra-ocular infection as it penetrated the blood-aqueous barrier the most readily

Mr DEREK AINSLIE discussed the use of polymyxin, which has a powerful bactericidal effect against the gram-negative bacillary organisms He had found it suitable for subconjunctival injection, and, when given in this way, it was effective against both experimental and clinical infections of the cornea due to the destructive *Pseudomonas pyocyanea*

In the discussion Dr. G SAUBERMANN (Switzerland) said that intra ocular infections could be treated with aureomycin given intravenously, and Dr HENRI MILLER (France) stated that he had found that the application of antibiotics to a scarified area of the sclera induced intra ocular penetration

Other Topics

Mr C DEE SHAPLAND described changes in the refraction of the eye following the operation of lamellar scleral resection Mr R A WEALE discussed some aspects of total colour-blindness, concluding that cone-monochromatism was a defect which must be located not in the retinal receptor layer but in a more central zone Mr F R NEUBERT showed a large number of excellent photographs of vascular patterns on the eye and discussed their significance

Mr E S PERKINS described a simple applanation tonometer, and Dr ALEXANDER E MACDONALD dealt with the practical application of topical cortisone

---

Reviews of Books

Lectures on the Scientific Basis of Medicine

Vol. I 1951–52 Delivered to the British Postgraduate Medical Federation London University of London, The Athlone Press 1953 Pp 396 30*s*

NO medical man, however specialised, could fail to find something to interest him in this book, and many, because of their specialisation perhaps, will want to read it from cover to cover For here are 18 lectures drawn from the first series of 39 given during the winter of 1951–52, on the scientific basis of medicine The title of the whole series may not have been too happily chosen, for it could alienate those who look on medicine as an art, with some scientific accretions, but in spite of the title, it is to those that we would specially recommend this book, for its demonstration that the actual contributors to the scientific aspects of medicine are so often themselves informed by values not "scientific" in any narrow sense Here Adrian, Dodds, Jefferson, Mackintosh, and Macfarlane are perhaps outstanding Both title and book should make their own appeal to the medical scientist, of whatever seniority, the beginner will find perspective and inspiration, the labourer in a narrow field will be refreshed by wider vistas, and even the doyen of medical science can read the other man's contribution, and be redeemed from narrow pride in his own achievements Those of the idler sort may be gratified by what seems to be a negative correlation between the excellence of individual articles and the number of references at their tail, after corrections have been applied for the length of the article itself and the volume of literature "at risk" in the field covered, for it seems a proper saying of Bacon that "books must follow sciences, and not sciences books."

Psychoanalysis Evolution and Development

CLARA THOMPSON, M.D, with the collaboration of PATRICK MULLAHY London Allen & Unwin. 1952 Pp 252 18*s*

IN the United States deviations from Freudian psychoanalysis have been numerous and influential Their sponsors have mostly tried to introduce more regard for social and cultural factors than Freud displayed or conceded; consequently less weight is given to innate instinctual forces bedridden. He is a frail thin old man, blind in his left eye, which was injured in childhood. Moderate dorsal kyphosis and signs of chronic bronchitis. No other relevant findings except in the nervous system. Grimacing movements of face and head, and slight athetoid movements of all four limbs, worse when he is unoccupied. Cranial nerves normal apart from moderate bilateral nerve deafness. No nystagmus. Slight increase in tone in arms. Abdominal reflexes present. Flexion contracture of left hip with internal rotation, flexion contracture of left knee, left talipes equinovarus, right leg held in extension with permanent equinus deformity of foot. Much wasting of legs with almost complete absence of left calf muscles. Continual writhing movements of legs, especially toes. Tone very spastic. Power diminished generally, movements of feet restricted by contractures. Knee-jerks very brisk and equal, sustained right ankle clonus; owing to contracture absent left ankle-jerk. Both plantar responses extensor. No sensory loss.

II 3.—Female. Said to have been severely crippled. Never able to walk, but could crawl as a child. Developed pulmonary tuberculosis. Died at 23.

II 4.—Female, aged 61. First had pain in legs at age of 9. Used to fall and could not get up. Remembers having to be helped to school. Legs became stiff and weak soon afterwards, and condition became gradually worse; by the age of 18 she was unable to walk or stand. She could crawl for a further two or three years, but has been bedridden since, and has spent the past fifteen years in various institutions. Has had pain in the legs and thighs, which have gradually become immobile and fixed. Manipulation under anæsthesia eleven years ago caused a fracture of the left femur, which has not united. Her arms have remained unaffected, and she has been in good health otherwise. No urinary symptoms. She is thin and pale. Blood-pressure 260/160 mm. Hg. No other abnormality in the heart, lungs, or abdomen. Cranial nerves normal. The muscles of the upper limbs are thin, but there is no localised weakness or wasting. Deep reflexes brisk and equal. Trunk and abdominal muscles apparently in spasm, abdominal reflexes absent. Gross generalised wasting of all lower-limb muscles, with fixation of knees in full extension, and ankles in plantar flexion, there being some subluxation backwards of the left ankle. Shortening of left thigh from ununited fracture. Slight movement only of both hip-joints. There is spastic paralysis of lower limbs with contractures, and no deep reflexes or plantar responses can be elicited. No sensory loss. No tremor or movements.

II 5.—Female, aged 59, healthy. Blood-pressure 180/90 mm. Hg. No neurological abnormality or other abnormal physical signs found on examination. Married but childless.

II 6.—Male, aged 53. First had stiffness of both legs at age of 10. At 14 arms similarly affected to a slight degree and painful after manual work. He was in Papworth Sanatorium with a left pleural effusion at the age of 20. Stiffness of the legs has become gradually worse, but he can still proceed at a reasonable speed with the aid of a stick. He has noticed slight unsteadiness on his feet in the past eight years, which he associates with the weakness, particularly when he tries to do anything quickly. About five years ago he noticed a tremor of both lower limbs and of right hand, and to a slight extent of left hand. Slight frequency of micturition during the past few years, but no difficulty in controlling his bladder.

A healthy-looking well-nourished man. No abnormality except in the nervous system. Fundi and cranial nerves normal. Immobile expressionless face. No nystagmus. Slightly increased tone in the right upper limb, but tendon-reflexes equal. Slight intermittent tremor of parkinsonian type of right thumb and index finger. Abdominal reflexes present but sluggish, and trunk muscles appear normal. Very slight symmetrical wasting of whole of both lower limbs. Bilateral pes-cavus deformity reversible by pressure on soles of feet. Slight involuntary irregular non-repetitive writhing movements of athetoid type of feet and toes. Gross spasticity of both lower limbs. Exaggerated knee and ankle jerks and extensor plantar responses. No sensory loss. Treatment with 'Artane' has enabled him to walk more rapidly and without the aid of a stick, and on examination there is considerable reduction in the stiffness of his lower limbs, which was presumably in part due to extrapyramidal rigidity.

III 1.—Male, aged 26, healthy. Good physique; no abnormal signs found on examination. Police officer.

III 2.—Male, aged 22. Good physique; no abnormal signs found on examination. Serving in Forces.

III 3.—Female, aged 18. A relation noticed that she walked awkwardly, dragging her right foot, at the age of 5. Shortly afterwards dragging of left foot appeared, but less severe. These symptoms have got slowly and progressively worse; she now walks slowly with a shuffling gait and cannot walk for more than half a mile. She can cycle for long distances and runs a small sweet-shop. About a year ago she noticed that her right foot "draws up" at night. This consists of the foot becoming dorsiflexed at the ankle, also assuming the cavus position, causing discomfort; these spasms last several minutes and wake her from sleep. Recently she noticed writhing movements of the toes of both feet, similar to those of her father. General health good, and she has had no other illnesses of note.

A healthy-looking girl with no abnormalities other than in the nervous system. Her cranial nerves, upper limbs, and abdominal reflexes are normal, but she does not swing her right arm freely when walking. The lower limbs show an unusual position at rest, the right foot being involuntarily dorsiflexed and curled up in the cavus position. The left foot is held in the neutral or slightly plantar-flexed position with some pes cavus. There is slight spasticity of the muscles above, but extreme spasticity of the muscles below, the knee and considerable force has to be used to move the ankle-joints at all, and to straighten out the pes cavus, which does, however, disappear completely when the action of the muscles is opposed. There is slight wasting of the whole of both lower limbs, with very slight weakness on movement at both hips and knees, worse on the left side than the right, and moderate weakness of movement at the ankles. Both knee-jerks very brisk and equal, but the ankle-jerks can only just be obtained, and the plantar responses cannot be elicited at all. Slight writhing movements of the toes of both feet. There is no sensory loss. The lower part of both legs, round the whole circumference, and the whole of both feet are bluish purple and always cold.

Treatment with artane enabled her to walk a mile without undue fatigue, whereas previously she could only walk a quarter of a mile with difficulty.

IV 1.—Female, aged 5 years, said to be healthy.

IV 2.—Male, aged 13 months, said to be healthy.

DISCUSSION

The chief interest of this family lies in the presence of associated extrapyramidal abnormalities. III 3 was the first to be seen and presented an unusual clinical picture. There was slight generalised weakness of the lower limbs, and the tone of the thigh muscles and the knee-jerks were only slightly increased, while on passive movement of the ankle-joint the impression was of lead-pipe rigidity. The ankle-jerks could barely be elicited, and the plantar responses could not be obtained. The writhing movements of the toes did not appear until later and, until the other members of the family were seen, it was not realised that the signs were due to a combination of spasticity and extrapyramidal rigidity. Three other members of the family had evidence of extrapyramidal lesions. I 1 was said to have a tremor of his right arm and "constant movements" of his great toes. II 2 showed grimacing movements of his face and also movements of his head which were usually non-repetitive and had an athetoid quality. He also had slight athetoid movements of all four limbs. II 6 had a somewhat expressionless face, a parkinsonian tremor of his right hand, and writhing movements of his toes and feet.

We have been unable to discover reports of any family in this country with extrapyramidal signs, although several examples have been recorded in France, America, and Germany. Ballet and Rose (1905) report one case, in a family with this disorder, who had choreiform movements and a tremor of the hands accompanying the spastic paraplegia. Mason and Reinhoff (1920) mention four cases with a coarse tremor affecting the jaw, tongue, arms, or hands. In a family reported by Bremer (1922) two members had grimacing tics; and of two cousins described by Guillan and Bize (1933) one had incessant choreiform movements of the head and hands. A further example of this association is a case (Jackson

Dr Thompson is most in sympathy with the teachings of Erich Fromm, Karen Horney, and Harry Stack Sullivan. Her contacts with Sandor Ferenczi, by whom she was evidently psycho analysed in Budapest, have also influenced her outlook. The first seven chapters of the book are devoted to a respectfully critical review of psycho analytic theory as developed by Freud, chapter eight is about "Deviants around 1912, Adler and Jung," and the ninth and tenth chapters deal with Rank, Ferenczi, Reich, Horney, Fromm, and Sullivan For the latest phase Dr Thompson has concentrated on developments in the United States, where psycho analysis has been more affected than elsewhere by social psychology and cultural anthropology the European scene and particularly English modifications and variants, are ignored Her account is clear, tolerant, and well-informed, though not penetrating it is a useful guide to the chief mutations which psycho analysis has undergone in America under the impact of criticism and external influences

Pharmacology in Clinical Practice

Harry Beckman, M.D, director, department of pharmacology, Marquette University Schools of Medicine and Dentistry Philadelphia and London W B Saunders 1952 Pp 839 63*s*

This valuable book will be welcomed by those who find difficulty in fusing the pure pharmacologist's version of his subject with the excessively empirical presentation found in many textbooks of therapeutics Dr Beckman's new publication is essentially a manual for clinicians, and his long experience as a practising physician and as a teacher have equipped him for the task Thus his frequent references to the limitations of drug therapy are realistic "I think," he says, "in terms of specific diseases and the opportunities they present to the pharmacologist, in terms of symptoms and not of anatomical groupings of organs or chemical groupings of drugs" He emphasises, too, that the practitioner does not "reason forward from the drug to the patient but from the patient and his malady to the drug" He has stripped the subject of any discussion of historical development and of the relations between chemical composition and biological activity, feeling that there is room for at least one book of this kind

The style is informal and makes for easy reading, though some may find the fairly common use of the imperative mood a little disconcerting The language is often vivid thus the section on cardiac arrhythmias begins "The heart, that amazing organ, begins whamming away before we are born and continues faithfully to do so until we wander out of this vale of tears" The segregation of the old fashioned materia medica (obstinately indispensable even for the most modern drugs) in a compendium enables him to avoid cluttering up the text with references to physical and chemical properties Perhaps he is over generous to research workers who have published rather vague conjectures, but he does not always take them seriously "speculation is fun and sometimes harmless" The book is lavishly illustrated, and the lengthy index has evidently been compiled with great care and with an eye on the needs of the practitioner

Twins

A Study of Three Pairs of Identical Twins Dorothy Burlingham London Imago Publishing Co 1952 Pp 94 35*s*

Most books on twins deal with the biological aspects of twinning and use the differences between identical and fraternal twins to study the part played by inheritance in the development of various qualities Miss Burlingham, however, is chiefly interested in the direct effect of being an identical twin on child development

The three pairs she studied in a war time residential nursery were unusual in that they had no normal family care The first two pairs entered at 4 months and were studied in detail till they were 3, the third pair spent most of their lives in another residential nursery and came under observation from $3\tfrac{1}{2}$ till 5 A residential nursery is no substitute for a home, but making allowance for this handicap to emotional development these studies show clearly that identical twins have special difficulties to overcome The most obvious is jealousy Rivalry between twins starts earlier and is more intense than that between an older and a younger child. This complicates the development of a happy relationship with each other and with the parents One pair were quarrelling so much towards the end of the study that they were separated Another difficulty is that these identical twins tended to turn to each other in all their troubles and to develop as a team withdrawn from their surroundings The chief temperamental differences between the twins was a tendency for one to become the active and aggressive member and the other the passive member of the pair But this rélationship was unstable and was reversed in one pair when the illness of the aggressive member allowed the other to take over this rôle

Miss Burlingham's study shows that one must be cautious in basing conclusions on the greater resemblance of identical than fraternal twins It is possible that the identical-twin relationship itself may be an environmental factor differing from the fraternal-twin relationship in ways important to emotional development

Pédiatrie

Robert Debré, Marcel Lelong Paris Flammarion. 1953 Pp 2234 Fr 14,500 2 volumes

This is probably the only European textbook of pædiatrics published in loose-leaf form, with annual revision It covers all the common diseases of infants and children likely to be met in temperate climates, but it does not touch on general subjects such as growth and development, nor the various aspects of child health

Infectious diseases are omitted, because they form the subject of another volume in the series, but there are good sections on vitamins and on the treatment of poisoning Short œsophagus and hiatus hernia are treated as distinct conditions, and it is surprising to read that pink disease has its maximum incidence between 3 and 4 years of age, but in general the authors are in agreement with current British teaching The book is beautifully printed and illustrated, and the short sentences and frequent subheadings make it readable

---

Frazer's Manual of Embryology (3rd ed Baillière Tindall, & Cox 1953 Pp 488 42*s*)—This was always the book of an individualist, and, in preparing the new edition, Prof J S Baxter has been at pains to preserve the character the late Prof J E Frazer conferred on it It is, as he says in his preface, "largely a record of the personal observations of one man extending over many years—and, indeed, is the only complete record of those observations that is available" The second part of the book, which deals with the development of separate organs and regions, is thus much as Frazer set it down The first part, which covers early and general development, Professor Baxter has rewritten to include the important advances which have been made in the past twenty years This is an improvement, for it was a former weakness of the book that its author sometimes ignored current work in his field Under the new hand the book maintains its distinction

Magicians, Theologians, and Doctors (London Edward Goldston 1952 Pp 293 21*s*)—The author of this work is Mr H J Zimmels, PH D, lecturer in Jewish history at Jews' College, London, and his studies in folk medicine and folk law are gathered from the Rabbinical *Responsa* of the 12th to 19th centuries Being decisions on cases taken from daily life, the *Responsa* serve two purposes for later generations to the rabbi, presumably, they are—or were—a guide for decisions in similar cases, to the historian they constitute a rich mine of raw material for research, since they deal with actual experience and are very careful in their presentation of facts The author has arranged his excerpts under various headings the education of doctors, theories on the causation and character of disease, therapeutics, remedies, surgery, and so forth The following quotation is an example of folk lore "Long nails cause sorrow Nails grow on the third day after being pared Therefore one should not cut them on Thursday in order to avoid their growing on the Sabbath" Treatment is largely of the magical kind, thus the liver of a mad dog is recommended as a cure for a man suffering from the dog's bite, and a patient with a bone stuck in the throat should have a similar bone laid on the nape of his neck The text, which is rather scrappy, is largely composed of this kind of material Nearly half the volume is occupied by bibliographic notes and references

1934) with a mask-like expression and a tremor of the head and right arm, three other members of this family with spastic paraplegia having no extrapyramidal abnormality.

Several workers have commented on the tendency for hereditary spastic paraplegia to appear at the same age in members of a particular family. Other families, however, have shown a wide diversity of the age of onset. In the second generation of the family reported here three of the five affected members were aware of the disease at the age of 9 or 10 years, whereas in the two more severely affected members it became apparent in early childhood. III 3 was also under the impression that her disease began at the age of 9. although her relations noticed its onset earlier. III 3 and II 5 had pes-cavus deformities which could be reversed with counter pressure as described by Garland and Astley (1950). Nocturnal flexion spasms, so typical of hereditary spastic paraplegia, only occurred in III 3 and were in dorsiflexion, not plantar flexion as is usual.

In generation II a striking facial resemblance was noticed among surviving affected members, conforming with a similar observation by Bickerstaff (1950). The only unaffected sibling, II 5, in this generation bore no resemblance to them in appearance or temperament, and was said to take after her mother. In certain families mental deficiency or progressive mental deterioration has been recorded. This family appeared to have average intelligence.

In view of the diffuse nature of the pathological process in those cases which have come to necropsy, it is not surprising that the clinical manifestations are often more widespread than the name of the disease suggests.

SUMMARY

A family is described in which there were seven cases of hereditary spastic paraplegia. In four of these there were associated extrapyramidal signs.

CORTISONE AS AN ADJUNCT TO SURGERY IN THE TREATMENT OF KELOIDS*

PATRICK CLARKSON
M.B. Lond., F.R.C.S.
CASUALTY SURGEON, GUY'S HOSPITAL; SENIOR PLASTIC SURGEON, BASINGSTOKE PLASTIC CENTRE AND ROYAL NORTHERN HOSPITAL

THE work of Ragan et al. (1949), Spain et al. (1950), and Baxter et al. (1951) has shown that in experimental incised wounds cortisone and corticotrophin (A.C.T.H.) can suppress all the elements of healing. Partly or completely they will suppress the exudative and cellular reactions of the first twenty-four hours and the capillary formation, fibroplasia, collagen deposit, and epithelial growth, usually seen between the fifth and twentieth days. Such granulations as are formed in the cortisone-treated wound lack the compactness of the normal granulation scar. These effects of cortisone are not influenced by the administration of vitamin C.

On the ground that a keloid is primarily a disorder of healing characterised by an excess deposit of intercellular substances, it seemed to me reasonable to try cortisone in the treatment of keloids. Conway and Stark (1952) had already reported promising results.

Keloids

There is difficulty about every aspect of keloids—definition, ætiology, and treatment.

DEFINITION AND HISTOLOGY

Alibert in 1810 is said to have been the first to use the term keloid to describe the clinical condition which we recognise by this name. He likened the extensions of the mass of scar tissue into the dermis and subcutaneous tissues to claws. To him a keloid was like a crayfish with legs implanted into and through the skin. It is not possible today to be much more precise than this loose descriptive definition. Although a major keloid may be distinguished easily enough from a typical hypertrophic scar, and both almost always from a fibroma, it is often impossible to distinguish with general agreement a hypertrophic scar from a keloid.

In all these three states collagen is an important constituent. In a typical keloid the collagen fibres are arranged in nodular masses which extend and grow irregularly into the surrounding dermis and subcutaneous tissues, where they blend into the surrounding normal collagen. In a fibroma the growth of collagen fibres is uniform and a capsule is created at the boundary with the surrounding tissues; there is no blending at the periphery between the collagen fibres of the tumour and the normal collagen bundles. Histologically as well as clinically a hypertrophic scar resembles a keloid more closely, but in it the collagen fibres grow more uniformly and tend to lie parallel to the lines of force across the scar. As in the keloid, however, these fibres blend with the surrounding normal collagen fibres at the periphery.

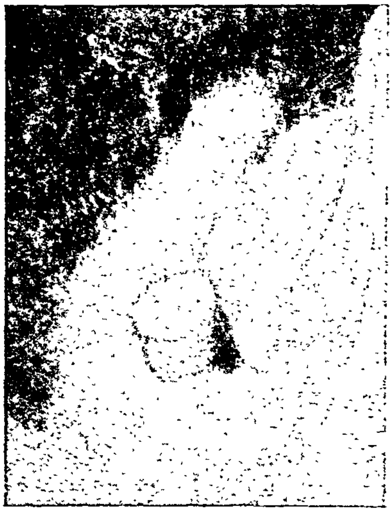

Fig. 1—Bulky keloid in lower part of mastoid scar developed in spite of irradiation in boy who had several normal scars elsewhere.

These descriptions of the three related states, and the distinctions between them, have been oversimplified here. They are true only of extreme examples of each, but the nodular arrangement of the collagen fibres and their peripheral blending seem to be useful in the histological definition of a keloid. Important constituents of both keloids and hypertrophic scars, in addition to the collagen which constitutes most of their bulk, are the fibroblasts and blood-vessels, which vary with the age of the lesions and contribute to their symptoms.

ÆTIOLOGY

Many clinical factors are known to be important to various degrees in the ætiology of keloids. They include pigmentation of the skin; infection; original cause of injury; site, direction, and depth of the scar; the age, and the metabolic and endocrine balance of the patient at the time of the injury.

Origin of Collagen

Collagen is the critical constituent of a keloid and accounts for most of its bulk. It has two possible origins.

THE LANCET

LONDON SATURDAY, MAY 9, 1953

Diet and Immunity

A DEFICIENT diet might be expected to impair resistance to infection, but undisputed immunological evidence of this is hard to come by

During the 1914–18 war vitamin-A deficiency was blamed for xerophthalmia among Danish children[1] Vitamin A was also found to be of value in puerperal fever,[2] but this has been disputed[3] In mice vitamin A has been reported[4] to increase resistance to mouse-typhoid infection, but no significant effect was detected by other workers[5] Results with members of the vitamin-B complex are equally conflicting There is some evidence that biotin deficiency may lower resistance[6] other experiments[7] show that vitamin-B deficiency has little effect, whilst some workers conclude that aneurine-deficient[8] and undernourished[9] animals are more resistant to virus infections, and pantothenic-acid deficiency increases resistance to pneumococcal infection[10] Again, with vitamin C it is difficult to assess the effect on immunity Guineapigs given cabbage daily respond better to active immunisation than those given mangolds,[11] but vitamin-C deficiency appeared to have no effect on the sickness-rates of Negroes[12] There is no conclusive evidence, either, that vitamin D has any effect on immunity Severe and long-continued protein depletion has been reported to have adverse effects on antibody production,[13] but the responses to immunisation of half-starved German civilians and of well fed British soldiers were remarkably alike[14] Diphtheria antitoxin production has been found to be as high in nutritionally deficient patients who had lost up to 40% of their body-weight as in well-nourished people[15] It is interesting to find, however, that pulmonary infections are relatively prevalent among the predominantly vegetarian Kikuyu, whilst arthritis is commoner in the meat-eating Masai tribe[16]

On the whole, therefore, the evidence suggests that most other physiological functions of the body are affected by diet before distinct effects on immunological response become apparent Some precision is given to this conclusion by the work of HOWIE, BARR, and GLENNY[17] on pregnant Scottish blackface ewes which were given two injections of diphtheria alum-precipitated toxoid (A P T) One group of ewes received a supplement of oats and linseed cake, whilst the controls were grazed on the same pasture but without dietary supplement Both body-weight and fleece-weight were higher in the ewes receiving the dietary supplement, and when the interval between the A P T injections was one month the serum-antibody titre was twice as high in the better fed group When, however, the interval between injections was two months the immune response was better, and it was not possible to detect any beneficial effect of the dietary supplement on the immunisation The serum-antitoxin content was followed for a year after immunisation In the first six weeks there was a rapid fall, this was followed by a slower decline, and a year later the antitoxin content had fallen to about 0 3% of the peak value when the interval between the injections had been one month, and to about 1 4% of the peak value when the interval had been two months

Newborn animals possess passive immunity, due to antitoxins obtained from the mother partly by antenatal placental transmission from the maternal blood-stream and partly by neonatal absorption by the suckling of colostrum The antitoxin titre of the colostrum at the time of birth is commonly much higher than that of the maternal blood-serum, presumably owing to selective antenatal accumulation of antitoxic globulins from the blood-stream, but a few hours after suckling has started the antitoxin concentration in the colostrum falls rapidly It has long been customary not to attempt the immunisation of infants during the first few months of life, in order to avoid the possible inhibiting effect of maternally transmitted antibodies on the development of active immunity in the offspring Unsatisfactory development of immunity has been observed in lambs given two injections of diphtheria A P T two weeks and six weeks after birth, when the amount of maternally transmitted antitoxin present was sufficient to combine with too high a proportion of the injected antigen[18] A third injection of A P T two months later resulted in satisfactory immunity

The Delphic oracle is no longer available for consultation, and the herd of goats which first drew attention to the magic of Delphi is dispersed, but we can learn from the Scottish blackface ewes and their lambs that for active immunisation the most effective interval between injections of the antigen is two months, that under these conditions diet has little effect on the development of immunity, and that routine immunisation with A P T should not be applied to infants during the first few months of life

Fig. 2—Keloids due to vitriol before (a) and after (b) standard method of treatment by excision plus irradiation.

(1) It may be formed by fibrillation or shedding of the cytoplasm of the fibroblast. This implies a limit to the amount of collagen produced by each fibroblast. The treatment of a keloid should therefore rationally be directed towards suppressing fibroplasia during its most active period in wound healing—say, from the fifth to the twentieth days. But this hypothesis is not in accord with the growth of keloids, which continues for weeks or months after primary healing. The pathological healing seen in keloids suggests that collagen is being formed in some other way.

(2) An alternative hypothesis is that collagen is produced by a chemical and enzymic process: the fibroblast secretes into the surrounding intercellular matrix enzymes which react with other substances there to form the adult collagen fibres. One possible mechanism, postulated by Meyer (1947), is as follows:

> "The young fibroblast secretes into the surrounding tissue spaces hyaluronic acid, a precursor of collagen, and chondroitin sulfate. By local acidification in the immediate neighbourhood of the cells the first fibres are produced by the polysaccharides from the native soluble collagen which denature into the insoluble fibre, on the surface of which lies a sheet of polysaccharide. With aging of fibres the polysaccharide layer becomes thinner and the hyaluronate is replaced more and more by chondroitin sulfate. Only in metabolically very active connective tissue like that of skin, hyaluronic acid production continues in considerable quantities. The role of ascorbic acid in the production of fibre formation may be that it is actually a component of chondroitin sulfate, replacing in the chain some of the glucuronic acid molecules."

The value of this hypothesis is that it conforms to the clinical course of most keloids. It implies that one fibroblast may be responsible for an indefinite amount of collagen. Further, cortisone is thought to act chemically, and we may reasonably suppose that the suppression of wound healing mentioned above is due at least in part, to a chemical inhibition by cortisone of some process similar to that postulated by Meyer. If this were so it would be necessary to give cortisone at any rate in maintenance doses, for a considerable period. But I must emphasise that I know of no direct chemical evidence that cortisone can react in any way with hyaluronate, native collagen, or chondroitin sulphate.

UNPREDICTABILITY

Fig. 1 shows a mastoid scar whose lower part is occupied by a bulky keloid which appeared and persisted in spite of early irradiation and recurred after I had excised it. The boy had other scars, none of which were keloid. Although keloids are without question more common in patients under 30, and in some types of patient (e.g., coloured patients), and although certain sites are more prone than others (e.g., outer shoulder and front of upper sternum), and although certain injuries are more likely to cause a keloid (e.g. acid burns), there is great variability between different people and in different scars on the same person. One patient, like this boy, may show a single keloid among normal scars. Another will develop keloids in several incisions, and then a later incision may heal quietly and cleanly to give a hair-line scar. This makes it very hard to assess any new therapy.

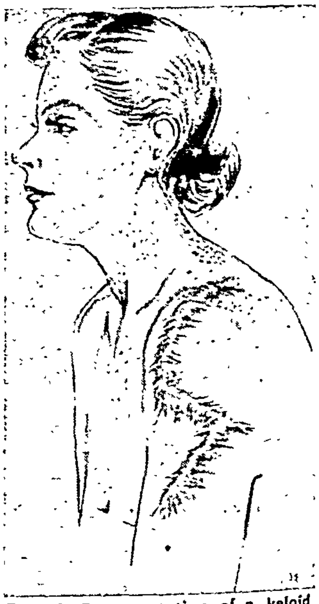

Fig. 4—Representation of a keloid following Z-plastic correction of vertical scar on shoulder. This keloid persisted two years in spite of irradiation.

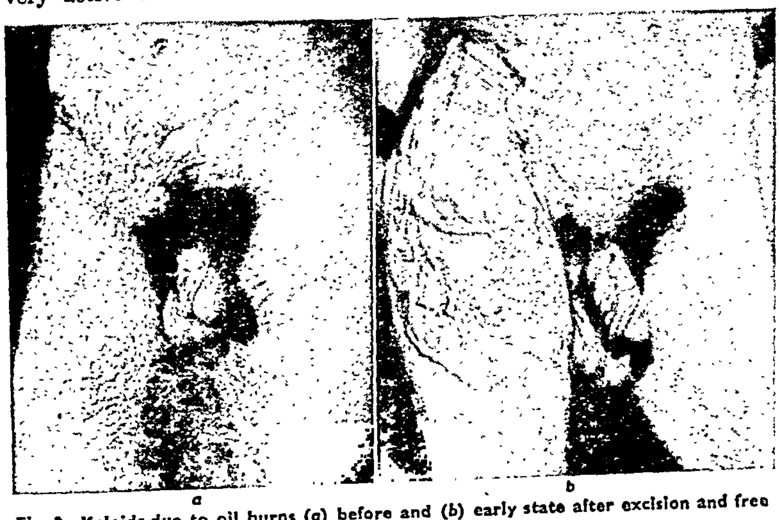

a b

Fig. 3—Keloids due to oil burns (a) before and (b) early state after excision and free graft cover.

Limitations of Standard Methods of Treatment

Fig. 2 shows a massive keloid, caused by vitriol from a rejected suitor, before and after treatment by surgery plus irradiation. The results cannot be called ideal The girl has a deeply pigmented line over her chest (the price of the otherwise beneficial X rays) and a flat, supple, and rather broad scar where the keloid was ; but this is nothing like so unsightly as it was before, and is symptomless.

Fig. 3 shows oil burns before and after treatment. The massive carapace of keloid left across the groin, thigh, base of penis, and scrotum was tender and itched constantly. It was excised, grafted at one operation, and completely healed a month after operation. The grafts are free from tenderness and itching. The patient has full extension at the hip; but

Symposium on the Thyroid

On Feb 25 the Society for Endocrinology combined with the section of endocrinology of the Royal Society of Medicine to hold an all-day discussion on the thyroid gland Meetings of this type serve a useful purpose in summarising the state of knowledge in a particular field, and perhaps even more by bringing together clinicians and workers in the fundamental sciences These two groups were about evenly represented in the symposium, but it was evident that nearly all the active research on this gland is at present coming from the biochemists They had a particular triumph to celebrate in the isolation and chemical and physiological characterisation of 3,5,3′-triiodothyronine

The credit for this biochemical feat of arms belongs to GROSS and PITT-RIVERS,[1] whose accounts of it began to appear towards the end of 1951 At the same time ROCHE and his colleagues across the Channel were pursuing independently a similar line of inquiry, and would no doubt have soon reached the same conclusions This piece of research illustrates so well the effectiveness of modern techniques in able hands that the salient points are worth restating The key technique in this instance was the combination of paper chromatography with the use of the radioactive isotope I^{131} Material from an animal which has received this isotope can be simultaneously analysed for all its iodine-containing compounds The starting-point was serum from a patient who had received a therapeutic dose of I^{131} Chromatograms made a few days after the dose revealed not only the expected thyroxine, but also another iodine-containing substance which was quite clearly different This unknown substance was eventually proved to be 3,5,3′-triiodothyronine, by synthesis and comparison of the natural and synthetic products by means of crystallography Interest now centred on the physiological properties of this substance When tested in rats by the goitre-prevention method it proved not only to have thyroxine-like properties, but to be about five times as active as thyroxine Several further comparisons between thyroxine and triiodothyronine were described at the meeting Triiodothyronine has been shown to be the more potent of the two in increasing the metabolic rate of mice, in promoting growth in thyroidectomised rats, in preventing the appearance of thyroidectomy cells in the pituitaries of rats on thiouracil, and in preventing the escape of radio-iodine from chick thyroids In addition, it is now known to be more potent in the treatment of human myxœdema (although in this respect it has no particular practical advantages) FOLEY, on the other hand, has observed that triiodothyronine is less effective than thyroxine in promoting milk flow in cattle

Biochemists now have an enormous amount of information about how the thyroid hormone is made, quite a lot about how it is released from the gland and transported in the blood, and almost none about its fate after it has disappeared into the peripheral haze, and even the form of the substance which acts on the peripheral tissues is in doubt PITT-RIVERS inclines to the view that thyroxine loses an iodine atom somewhere in the periphery, and that the triiodothyronine thus formed is the agent promoting the changes that we have come to regard as characteristic of the thyroid hormone ROCHE, on the other hand, has found that the two substances are formed at an approximately equal rate in the thyroid, suggesting that either or both may influence tissue metabolism MACLAGAN, in an admirably lucid paper, put forward some odd observations on the effect of thyroxine antagonists of the type of *n* butyl 3 5 diiodo 4-hydroxybenzoate (B D H B) In suitable doses this substance abolishes the effect of exogenous thyroxine on the oxygen consumption of mice, and given by itself it produces a small but significant depression of oxygen consumption When given with triiodothyronine, B D H B not only fails to reduce the rise in oxygen consumption, but actually increases it slightly The fact that B D H B counteracts the action of thyroxine, but not of triiodothyronine, suggests that it prevents the conversion of the former substance into the latter, thus endorsing PITT-RIVERS's view that triiodothyronine is the substance which acts on the tissues B D H B can thus be pictured as a competitive antagonist which interferes with the action of whatever enzyme is concerned in removing an iodine atom from the molecule of thyroxine It is, however, much more difficult to explain the apparent enhancement of the efficacy of triiodothyronine by B D H B MACLAGAN's suggestion that B D H B prevents the de iodination of triiodothyronine (as well as that of thyroxine) involves the assumption that triiodothyronine is de-iodinated after it has acted on the tissues, de-iodination is thus pictured as a step in the process of getting rid of used hormone, rather than as an essential part of hormone action This may be true, though the fact that de-iodination and hormone action occur more or less concurrently has probably led most people to suppose that the loss of iodine atoms is an essential part of the action of the hormone Clearly the de-iodination in vivo of organic iodine containing compounds deserves greater attention from biochemists than it has so far received So far, the only de-iodinating enzyme whose properties have been defined is that found by ROCHE and his colleagues in the thyroid itself This acts only on mono and di-iodotyrosine, and has no action on thyronine derivatives ROCHE has sought other enzymes in extra-thyroid tissues, but so far without conspicuous success

It was evident at the meeting that biochemists are fully aware of this and other obscurities, as problems become defined the appropriate techniques will be brought into action, and before long there will be further advances in knowledge to record But it was difficult to feel equally optimistic about the solution of clinical and pathological problems, the outstanding example of which is the ætiology of Graves's disease The solution of this problem could scarcely fail to throw light on other examples of endocrine overactivity Indeed it might also help to elucidate other diseases whose ætiology is at present equally obscure, such as rheumatoid arthritis and ulcerative colitis Yet progress in the investigation of Graves's disease has been negligible, and it is hard to discern any vigorous effort in this direction One cause is the lack of a satisfactory method of

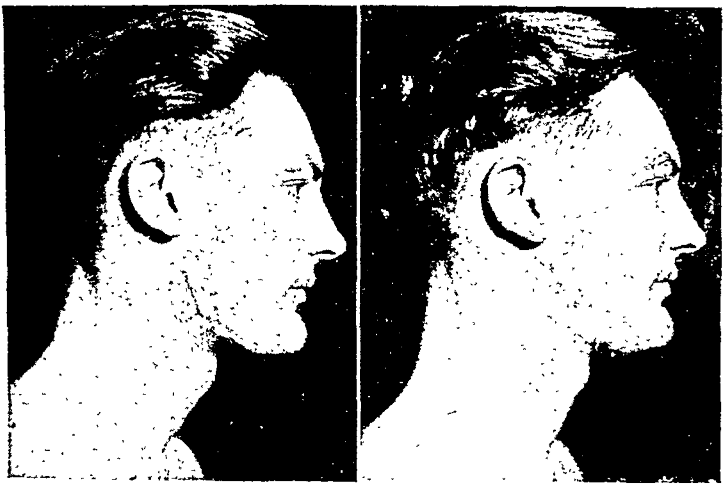

Fig. 5—(a) Result (in spite of preoperative and postoperative irradiation) of excision of keloid, due to acne and repair with Wolffe graft, and after (b) re-excision and cortisone therapy. The patient can now shave over the scar.

the appearance especially of the border scars, is not that of a normal thigh and groin.

Fig. 4 shows the sort of disaster which can follow radical surgery, even when it is supported by intensive irradiation, if the patient is one with a definite keloid tendency in the region of the scar. The massive unsightly tender itching scar which followed my Z-plastic correction of a vertical scar over the deltoid muscle persisted in this state for over two years.

Treatment with Cortisone

In any plan of treatment based on the use of cortisone the importance of the observation of Spain et al. (1950) that it has no effect on established granulation tissue must be emphasised. There are no theoretical grounds for the belief that systemic or local cortisone, or A.C.T.H. with or without hyaluronidase, can remove the mass of the keloid. Published reports (Conway and Stark 1952) confirm this, although relief from symptoms of tenderness and itching has been claimed. It therefore follows that the first stage in treatment with cortisone is removal of the mass of keloid plus an appropriate plastic repair of the defect. It is the subsequent healing which is controlled with cortisone. What is attractive about this plan of attack is that a critical feature of the result must always be the quality of the surgery, both of plan and of technique.

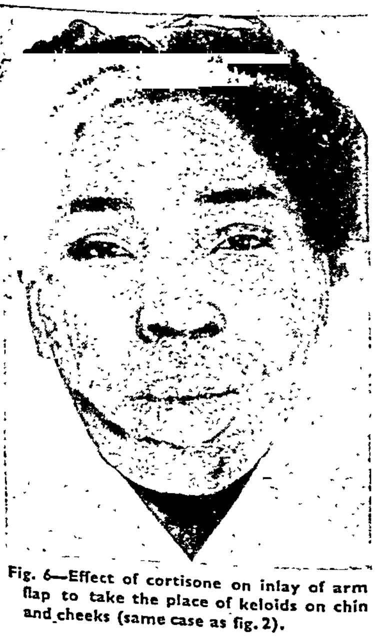

Fig. 6—Effect of cortisone on inlay of arm flap to take the place of keloids on chin and cheeks (same case as fig. 2).

Conway and Stark (1952) report two successes by this combination and one at least of those depicted in their photographs is a very considerable therapeutic triumph. Their experience of local injection of A.C.T.H. with hyaluronidase showed that only symptomatic, not structural, relief could be obtained. Polson and Pattee (1951) report a complete failure in a sternal keloid treated by excision plus large doses of cortisone.

Of my own 8 cases only 3 could be classified as major keloids. The others might be better called hypertrophic scars. 3 of the 8 were due to burns, 3 to acne, and 2 to trauma of the outer upper arm. The age of these keloids at the time of treatment varied from five years to six months. 4 of the 8 had resisted previous surgery plus irradiation. The longest any case has been followed up after my treatment is eighteen months, and the shortest twelve months. 5 cases were treated with systemic cortisone 100 mg. daily from the fifth to the fifteenth or the twentieth days. This late and moderate dosage of cortisone was chosen to avoid the risk of wound disruption and general symptoms. 3 cases were treated with local cortisone—cortisone acetate about 25 mg. daily from the fifth to the fifteenth days. One of these cases treated locally had to have the viscous cortisone acetate evacuated from under the wounds. All 8 cases had full penicillin cover for six days or more. Whenever possible, undermining was restricted to the very minimum necessary for closure. Serum-proof silk was used for skin closure.

Of the 5 treated with systemic cortisone plus surgery 1 is a good result, or at least eminently satisfactory to me (fig. 5). The scars of the cases treated systemically were undoubtedly smaller, of better appearance, and without symptoms after surgery; but it is impossible to attribute this effect with certainty to the cortisone. Of the 3 scars treated with local cortisone 2 gave good results in that the scars were flat, pale, supple, and inconspicuous, and caused no symptoms, but the 3rd gave a poor result, the scars being still easily noticeable on the face.

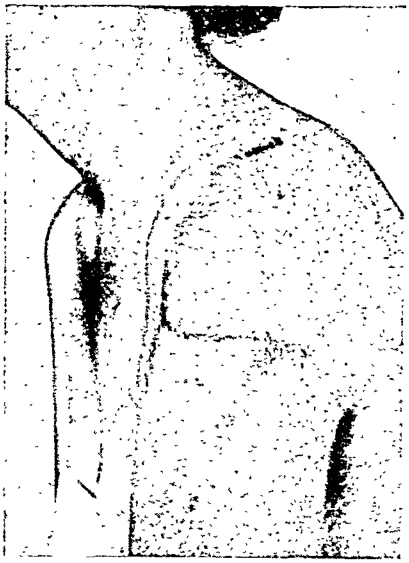

Fig. 7—Effect of cortisone therapy after excision of keloid shown in fig. 4. The scar is smaller; there is less itching and tenderness.

In 2 of the patients treated, euphoria and retention of water were observed. These toxic effects were temporary and ceased on withdrawal of the cortisone. In all the cases the relative lack of reaction round the skin sutures and of suture marking was noted.

Fig. 6 shows the result of cortisone therapy in the keloid due to vitriol (cf. fig. 2), and fig. 7 in the scar over the deltoid muscle (cf. fig. 4).

Conclusions

The only reliable evidence remains the reported effects of cortisone on experimental incised wounds. No unequivocal evidence has been published, and none is presented here, that cortisone has any consistent effect on keloids; but in the present short series it does inducing thyrotoxicosis in animals This condition can of course be produced by giving thyroid or pituitary extracts, but such a procedure tells us nothing useful about the cause of Graves's disease The only claim to have produced a convincing replica of Graves's disease in animals comes from BANSI and his collaborators,[2] who state that wild rabbits, when freshly caught and caged, regularly develop a condition resembling thyrotoxicosis They show tachycardia and exophthalmos, waste rapidly despite a good intake of food, and usually die within a few weeks Both the uptake of radio-iodine and its subsequent discharge are much greater than in tame rabbits Microscopically the animals' thyroids show distinct hyperplasia The syndrome can be prevented by the administration of anti-thyroid drugs The case for regarding this syndrome as comparable to Graves's disease in man is substantial, and it is therefore all the more regrettable that no attempt seems to have been made to repeat the observations outside Germany The experimental procedure—which demands, it would seem, some acquaintance with the poacher's art—can scarcely be described as a convenient laboratory technique, and it is perhaps for this reason that it has aroused so little interest in this country

The failure of clinicians to investigate vigorously the ætiology of Graves's disease can largely be ascribed to the efficiency of modern methods of treatment The prime stimulus to research comes from dissatisfaction with the status quo, and it is not easy to feel dissatisfied when a disease can be readily controlled by various methods of treatment All these methods are essentially empirical and none is radical, but their only major failing, from the practical point of view, is their relative inability to control the ophthalmic symptoms Nevertheless no-one should feel content with these methods, which achieve their object only by battering the overactive thyroid into submission—whether the weapon employed is surgical, pharmacological, or radiological The manic can be kept quiet with leg-irons and handcuffs, but such contraptions are not regarded as instruments of therapy We need to know what makes the overactive thyroid go wild, only with this knowledge can we hope to evolve a method of treatment deserving the name of "cure"

The Ghost in the Machine

AN intelligent member of our profession once had the opportunity, with his family, of watching from his Hampshire home a display of the aurora borealis His family quickly identified the phenomenon, but the doctor, feeling too scientific for that, attributed the glow in the sky to a fire down Portsmouth way, and shortly afterwards was able to smell the smoke He used to say that this illustrated the effect of a hypothesis on the scientific mind

His was an erroneous hypothesis, but even a hypothesis which turns out to be largely correct, and illuminating—like the theory of evolution—can lead us into extravagances It is as though, having seen an inch or two into the millstone, we feel obliged to declare we have seen through the whole thing This characteristic of the scientific mind, so irritating to laymen, has justifiably annoyed Dr F M R WALSHE[1] as well In his Hughlings Jackson lecture to the Royal Society of Medicine, last December, he complained of some notions derived from cybernetics now infecting neurophysiology, which can be summed up (in his phrase) as "nerve nets can know universals" He quoted the statement of PITTS and MCCULLOCH[2] that

> "The basic premise of philosophical idealists and realists and of scientific naturalists and mechanists to the effect that natural and biological systems can have neither knowledge of universals nor normatively defined and behaviour-controlling purposes must be rejected A teleological system can be, and in human nervous systems it is, a mechanical system in which the behaviour of the system is controlled by a negative feedback over the goal"

But, as WALSHE points out, the term "universal" has a long and striking history in the grammar of metaphysics "Expressed in its simplest form the Universal is *one thing common to many*" To know universals, he says, is to know two things it is (1) to know the nature, essence, or being of things—i e, to know that which is the essence of a thing without which it would not be what it is—and (2) to be able to recognise and predicate common qualities of singular things In the light of this definition he criticises another quotation from *Perspectives in Neuropsychiatry*, which states

> "A self-re-exciting loop of neurones, sharing neurones with other loops in which reverberation can be set up by the entry of afferent impulses from different sense receptors, gives and preserves the association between particular events and allows the recognition of a universal to be sparked by the receipt of a particular"

But, WALSHE argues, the mental recognition of a universal is the recognition of a reality which is not individual However complex the activities of the neuronal circuits, their stimuli are and remain individual and even material "No amount of 'sparking' in the circuits can produce a concept of something which of its nature transcends the individual" The late C E M JOAD made the same point in his last book[3] It is extremely difficult, he said, to see how what is commonly called an abstract thought could depend, even at several removes, on a sense object, "for how could an historical generalisation be the result of a physical stimulus?"

There is another difficulty not mentioned by WALSHE or JOAD which seems to us of interest What do we mean when we speak of "knowing" universals? A man when he "knows" a universal is consciously aware of it, or can become consciously aware of it by directing his attention to it, moreover, unless he is *consciously* aware of it—or, at any rate conscious—he cannot act upon it in the second of WALSHE's senses that is, he cannot use it to recognise and predicate common qualities of singular things A machine working on the principle of negative feedback can act on the resultants of past experience without consciousness (though, as WALSHE points out, the computations of even the most able machine remain meaningless without a human intelligence to read off the symbols) Without consciousness, appear to have helped considerably in preventing the recurrence of keloids. It is also quite clear that, at some levels of dosage and length of administration, cortisone has little or no effect.

[3] The Recovery of Belief London Faber & Faber 1952 Pp 250 15*s*

Further trials should, I believe, be directed towards the investigation of what is the best dosage and best type of extract—cortisone or A.C.T.H., local application or pellet implantation, administration by mouth or by injection. Almost certainly longer treatment than that given to these cases will be necessary. Perhaps consistent local effects in the treatment of keloids can be obtained only with toxic amounts of cortisone. Whatever permanent rôle may be found for cortisone, we must suppose that its use will have to be preceded by a surgical excision of the keloid and a properly planned repair.

Of my 8 patients the first 4 were treated at the Queen Alexandra Hospital, Millbank, where it was possible, through the courtesy of the Officer Commanding, Colonel J. O'Meara, to obtain cortisone for this work. At Millbank the cortisone treatment was administered and supervised by Captain Ian Cran, R.A.M.C. Others of these patients were treated at Guy's Hospital in conjunction with Dr. Kenneth MacLean, on whose advice I have relied for control of the systemic effects; and in a further case I have been aided in the same way by Dr. Desmond MacManus. I take this opportunity of expressing my appreciation of this help, and to Dr. S. de Navasquez, morbid histologist to Guy's Hospital, who has constantly guided me on the pathological aspects of the problems.

KELOID, A HAZARD OF PIERCING FOR EAR-RINGS

C. J. CELLAN-JONES
M.D. Durh., F.R.C.S.E.
SURGEON, SWANSEA GENERAL HOSPITAL, GLAM

THE conventional pattern of surgery is occasionally relieved by some bizarre condition which surprises even the most seasoned practitioner. Relying on his experience he considers the case unique until medical literature reveals, to his chagrin, that the nonesuch is almost a commonplace.

CASE-RECORD

Early in 1949 Mrs. A, who is now 28, had her ears pierced by a layman, and plain gold rings were inserted. No significant inflammation arose, and three months later the same rings were used by a friend, who has noticed no subsequent abnormality.

In 1950 the patient was found to have pulmonary tuberculosis, and thoracoplasty was performed by Mr. Dillwyn Thomas. Whilst she was in hospital, the lobes of both her ears became tense, and painless nodules increased so rapidly in size that she could no longer wear her ear-rings.

Photographs taken after my first examination, on Oct. 14, 1952, showed sessile tumours resembling button mushrooms in front of and behind both lobules, the condition being worse on the left side. Radiographs of the lungs did not disclose any active tuberculous focus, and the sputum was negative. The long and soundly healed scar over the thorax was, however, distinctly keloid.

On Oct. 28 the tumours were removed from both ears under general anæsthesia. Because each of the nodules was densely hard, none of the overlying skin could be preserved to repair the resulting defects, and suturing was therefore done secundum artem. Healing took place without incident, and today the cosmetic appearance is surprisingly normal.

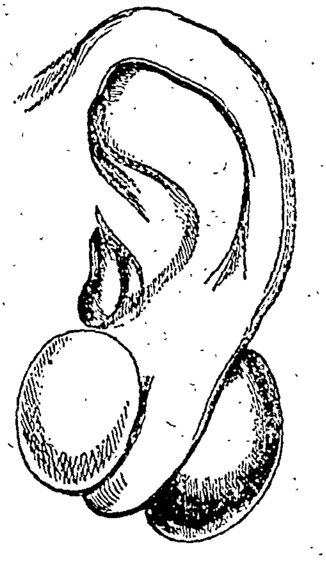

Fig. 1—Hilton's case.

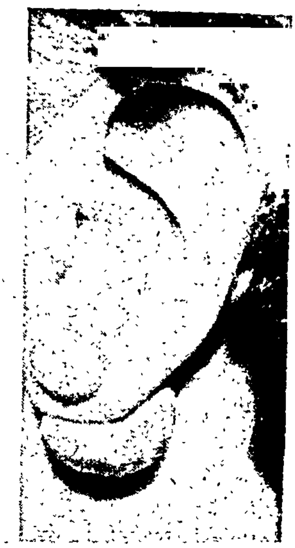

Fig. 2—Present case.

Dr. A. F. Sladden reported on the tumours as follows: "The tumours have a fibromatous structure with good vascular supply. The central portion of each lobule contains areas of densely packed fibres surrounded by a zone of looser texture. Between this and the overlying epithelium there is a narrow zone showing few hair follicles and sebaceous glands and containing small foci of inflammatory cells. The appearance suggests compression of the skin layers by the actively growing central tissues. No nerve structures are present, and there are no neoplastic cells and no signs of tuberculosis. The general structure corresponds closely with the textbook description of keloid, and it therefore seems probable that the tumours are true keloids rather than simple fibromata."

DISCUSSION

It appears from published reports that such tumours were commonest during the middle and later years of the 19th century. One author of that period accounts for its prevalence by a suggestion that "when trade is good factory-hands seem to delight in the barbarism of irritating their ears with cheap and bad jewellery." Knapp (1876) also felt that the danger lies in the rings themselves, for he emphasised "the harmful galvanic action of the alloyed metals." The fallacy of this exploded theory is demonstrated by my patient, since the ear-rings which appeared to cause tumour formation in one person produced no harmful effect in another.

Fig. 1, reproduced from an article describing a case under the care of John Hilton (*Lancet* 1860), resembles quite strikingly the photograph of my patient (fig. 2) and supports the generally accepted view that these tumours are bigger behind the auricle. Hilton's treatment was excision of the lobes, because of a common belief that the condition was "semi-malignant." No pathologist has yet found evidence of malignancy, however, and recurrence after local resection of the tumours probably results from their incomplete removal.

With the passage of time it has become evident that these tumours, formerly regarded as fibromata, are in fact typical manifestations of keloid scar tissue, and my case strongly supports that view. I was particularly impressed by Brennan's (1929) description of a Negress with enormous keloid masses springing from tribal markings on the lobes of both ears. His patient also had a pronounced keloid scar on her upper arm.

Keloid scars are known to arise more commonly in tuberculous patients. In view of the history of tuberculosis in my patient it would be interesting to know then, the mind is less efficient than a machine, even though all the mechanical structures of the brain and nervous system remain intact These considerations are so striking that no mechanical analogy seems to us equipped to explain them fully

WALSHE cautioned his hearers not to be intimidated by the current of authoritative opinion now setting in favour of a physical and statistical account of mind, since we may easily take the evidence too seriously and allow the frailty of the logic to escape our notice. This is harsh criticism of a sincere body of thought, nevertheless it does seem possible that the determinists have not noticed quite where their argument is taking them For if we are all determined together it is hard to imagine what critical value attaches to any of our opinions Given a correctly selected set of facts a calculating machine can give the right answer to a problem But the facts supplied to the human machine, we must (if we are determinists) assume, are selected only by the random circumstances of the environment Moreover, the machines are fallible a man may see a mirage and take it for a lake, or hear an owl's screech and take it for a human cry, he may also be supplied with inaccurate data by other fallible machines in his circle We must therefore expect an extremely wide range of answers to his problem, all of them "right" and some of them conflicting The determinists may, indeed, be "right" in some more absolute sense than this, but if they are it can only be by accident, as it were—much as the prophecy which comes out of a fortune-telling machine may occasionally hit the truth And again, if they are right, they leave us nothing to do but sit back, like old-fashioned Marxists, and wait for history to take its course All this might not matter very much, but should they in fact be wrong, and yet succeed in convincing us that they are right, then we might easily—by an act of free-will—give up doing anything useful at all, on the erroneous assumption that we could leave everything to the machine

The picture WALSHE draws of scientists anxiously trying to cram Nature into too small a portmanteau, and refusing to believe that it cannot be made to shut, could not have been imagined before the middle of the last century Before that, philosophers regarded all knowledge as their province, and were willing to go where truth led, even if it took them to the boundaries of metaphysics The natural scientist of today, WALSHE says, "tends to shrink back in his quest for truth when the possibility dawns on his mind that perhaps after all the ancient concept of the soul is not yet dead, and may once again have to be evoked to account for the activities of the human mind " He himself boldly, even defiantly, declares for the soul Defiance, however, seems hardly necessary The mind considering the religious view of the universe is not faced with a choice between what is clearly true and what is clearly false, or obliged, by a painful and crippling leap, to achieve belief in the incredible Rather it is faced with two descriptions of Nature, both all but impossible of belief Is it any harder—or any easier—to believe there is a primary cause for the continuous creation of worlds than that there is no cause at all? (Incidentally, it is surely interesting that determinists, those sticklers for causation, should prefer no cause at all to a first one) The more scrupulous the mind the less readily will it be able to choose between these hypotheses, and after long weighing of both the most it may be able to affirm is that one belief seems slightly less improbable than the other

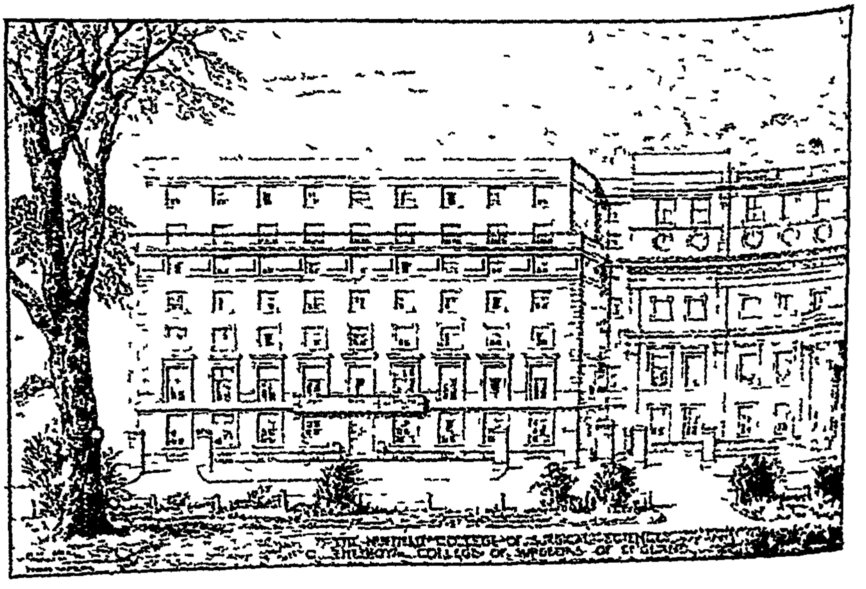
---

Annotations

THE SURGEONS BUILD

GREAT disasters should be followed by great recoveries The Fire of London gave us St Paul's and many another fine thing, and it is for us to ensure that the eventual result of the bombing will be to enrich our city The Royal College of Surgeons suffered heavily in the war, but like a well-pruned tree may yet be the better for it When the Queen laid the memorial stone last Tuesday, the new buildings were springing up around her, and above the blue and white marquee we could imagine the ceiling of the great hall already closing over her head The building programme will not only make good the war time losses, but will provide noble quarters for all the scientific and educational duties of the college

The great hall seats 700 people, and in its austere and dignified design will be a fit centre for surgical congresses, lectures of the college, and receptions and other social occasions Three floors of museums will lie above it, given by the Wellcome Trustees, and these will be matched by three floors of laboratories, lying above a new council chamber The library is to be enlarged, and an exhibition hall will connect the old and new buildings Later the Nuffield College of Surgical Sciences, the gift of Viscount Nuffield, will rise facing Lincoln's Inn Fields, in which there will be all the amenities of college life for 90 resident postgraduate students from Great Britain, the Commonwealth, and abroad A department of



whether an appreciable percentage of those who develop tumours after ear-piercing have a tuberculous diathesis.

My sincere thanks are due to Mr. Tal Jones for his excellent photographs, and to Miss Wade, of the Royal Society of Medicine, for her help in preparing this article.

CHLORAMPHENICOL IN TYPHOID AND PARATYPHOID FEVERS

NEW LINES OF TREATMENT

A. H. El Ramli
M.R.C.S., D.P.H., D.T.M. & H.
DIRECTOR, ABBASSIA FEVER HOSPITAL, CAIRO

I HAVE previously reported on the curative effect of chloramphenicol in 200 cases of typhoid fever (El Ramli 1950). The recommended scheme of treatment was to give 50 mg. per kg. body-weight in the first two hours (loading dose), followed by 25 mg. per kg. twelve-hourly until the temperature became normal, and half that dose for fourteen days in convalescence.

Since then some further investigations have been made. (1) A new régime has been tried in which the initial loading dose was omitted and a smaller daily dose of chloramphenicol was given twelve-hourly. (2) The relation between treatment in convalescence and the incidence of relapse has again been studied. (3) The therapeutic value of chloramphenicol produced by different pharmaceutical firms has been compared. And (4) the therapeutic response to rectal administration of chloramphenicol in the form of suppositories has been assessed.

TABLE I—AGE-INCIDENCE OF ENTERIC FEVER IN PRESENT SERIES

Age (yr.)	No. of patients
0–5	*181 (*45·5%*)
6–10	75 (*18·8%*)
11–15	55 (*13·8%*)
More than 15	87 (*21·8%*)

*Of these patients only 4 were aged less than 2 years.

These observations were made in 398 cases of typhoid or paratyphoid fever admitted to the Abbassia Fever Hospital between February and September, 1952. Of these cases 81% were diagnosed as typhoid fever, 17·5% as paratyphoid A, and 1·5% as paratyphoid B. The diagnoses were based on the clinical picture, the isolation of the organisms from the blood, urine, or stools, and a rising Widal titre.

TABLE II—TREATMENT OF ENTERIC FEVER WITH DIFFERENT MAKES OF CHLORAMPHENICOL 12·5 MG. PER KG. OF BODY-WEIGHT TWELVE-HOURLY

Make of chloramphenicol	No. of cases	Average duration of fever (days)	
		Before treatment	After treatment
‘Chloromycetin’ (Parke Davis)	90	13·7	3·3
‘Synthomycetine’ (Le Petit) ...	108	13·6	3·7
‘Kémicétine’ (Carlo Erba) ..	200	13·8	3·9
Total	398	13·7	3·7

A few other cases have since been treated with ‘Microchlorina’ and ‘Alficetyn,’ other brands of chloramphenicol; results are similar to those recorded above.

The age-incidence of enteric fever in the present series is shown in table I. Of the 398 patients 45·5% were under 5 years of age, mainly between 2 and 5; 64·3% were under the age of 10; and only 21·8% were over 15.

FINDINGS

New Régime of Treatment

The dose used in the present series was 12·5 mg. per kg. twelve-hourly without any initial loading dose. This dosage gave a satisfactory response (see table II). The average duration of fever after the start of treatment was 3·7 days, compared with 3·5 days in the previous series (El Ramli 1950). All the patients received the daily dose in two equal doses. I now regard it as preferable to give the chloramphenicol twelve-hourly, for the following reasons:

(1) There is less interference with the patients' rest.

(2) The serum-chloramphenicol level is maintained higher than it would be if the daily dose (25 mg. per kg.) were given at shorter intervals, because each dose would then be smaller.

(3) The therapeutic response is the same whether the daily dose is given two-hourly, four-hourly, or twelve-hourly (El Ramli 1950).

Duration of Treatment in Convalescence

The patients in the present series were given chloramphenicol, after the temperature became normal, on three different lines:

Group I included 289 patients in whom chloramphenicol was given for 0–3 days after normal temperature had been reached; of these patients 26·3% relapsed (see table III).

Group II included 58 patients in whom treatment was stopped when the temperature became normal, to be resumed throughout the second week of convalescence, when relapses are expected; 13·8% of them relapsed. Smadel (1950) and John and Vinayagam (1952) favour this scheme of interrupted treatment in convalescence and report favourable effects on the incidence of relapses.

Group III included 51 patients whose treatment was continued for twelve consecutive days after their temperatures had become normal; 3·9% of them relapsed.

The results obtained show that the relapse-rate is much less where treatment is continued for twelve days in convalescence (group III). The reason why there were

TABLE III—RELATION BETWEEN DURATION OF TREATMENT IN CONVALESCENCE AND INCIDENCE OF RELAPSE

Drug used	Duration of treatment in convalescence (days)						Total	
	0–3 (group I)		7 after 7 days' rest (group II)		12 (group III)			
	No. of cases	No. of relapses	No. of cases	No. of relapses	No. of cases	No. of relapses	No. of cases	No. of relapses
Chloromycetin	51	16	19	4	20	1	90	21 (*23·3%*)
Synthomycetin	78	18	17	2	13	0	108	20 (*18·5%*)
Kemecetin	160	42	22	2	18	1	200	45 (*22·5%*)
Total	289	76 (*26·3%*)	58	8 (*13·8%*)	51	2 (*3·9%*)	398	86 (*29·7%*)

All the cases were observed for an average of 3 weeks after the temperature became normal, which it did in 2–5 weeks. Relapse took place after 10 days on the average (range 1–21 days).

anæsthesia will lie above it. Finally the south-western part of the existing college is to be reconstructed, to provide a fellows' common-room ground-floor lecture-rooms, and a department of dental surgery

In his address of welcome Sir Cecil Wakeley, president of the college, thanked Her Majesty, herself an honorary fellow of the college, for "thus recognising our endeavours to raise from the ruins of our old college a new home of English surgery" He mentioned the many donors whose generosity has made it possible for the work of rebuilding to go forward.

FARMER'S LUNG

In rural areas with a high rainfall, farmer's lung is commoner than is generally supposed and causes a good deal of minor illness among agricultural workers Fuller[1] has been able to collect 32 cases in eight years from the Devonshire area The disease appears in those who are exposed to dust from mouldy hay and straw Hay becomes mouldy when it has lain wet in the field after cutting The extra moisture encourages the growth of various moulds, and when the hay is handled large amounts of spore-bearing dust may be inhaled The cowman puts out fresh hay for the cattle each day, and when this is being done, says Fuller, it is impossible to see across the cowshed for dust The same thing happens during the threshing of ricks of oats wheat and barley which have been harvested in bad weather The greatest risk is to members of mobile threshing teams, who may be repeatedly exposed The risk is greatly reduced by the use of a combine harvester, when the corn is threshed as soon as it is cut

The disease is divided by Fuller into three stages In the isolated acute attack there is a sudden onset of fever at the end of the day of exposure The fever lasts only two or three days, and is accompanied by a cough with a little mucopurulent sputum which may be blood-stained Anorexia, lassitude, and frontal headache may last for several days after the acute symptoms have subsided. Moist sounds may be heard in the chest but there is no radiographic abnormality. The acute illness is so short that the patient does not always consult a doctor

The subacute phase, however, is more incapacitating and often brings the patient to hospital or chest clinic The majority of Fuller's cases were in this group They gave a history of repeated exposure to mouldy hay or corn during the previous two or three months They complained of increasing breathlessness with a short dry cough and bouts of fever in the evenings after exposure These patients were often cyanosed, but there was no bronchospasm or other evidence of asthma X-ray examination of the chest showed a fine alveolar mottling with evidence of compensatory emphysema. The symptoms cleared up in a month or two after the patient had been removed from contact with the dust, but the radiographic appearances remained abnormal for three or four months

The third stage is fortunately rare and develops only when the pulmonary changes have become irreversible The final picture of pulmonary fibrosis, emphysema, and bronchiectasis is indistinguishable from that of the other non-silicotic pneumoconioses, such as those found in cotton-spinners and bagasse workers

It is not clear how the fungus-laden dust gives rise to farmer's lung, and little is known about the morbid anatomy in the earlier stages Fawcitt[2] and Törnell[3] regarded the disease as a specific fungus infection of the lung, but, as Duncan[4] points out, the rapid recovery which follows removal from exposure does not suggest a progressive mycosis, and there is no good evidence that any of the fungi found in mouldy hay are capable of invasive spread within the lung The mere presence of fungi in the sputum means nothing for they are common contaminants Fuller found that 15% of unselected sputum samples contained moulds, including those commonly found in mouldy hay—a reminder of the importance of Koch's postulates Perhaps the mould spores and dust act as allergens, or as chemical or mechanical irritants, giving rise to a foreign-body reaction and miliary fungal granulomata This possibility is supported by the work of Zettergren,[5] who showed that when rabbits inhaled sterile threshing dust, mixed with the spores of *Candida albicans* one of the commoner fungi found in sputum and in mouldy hay, a characteristic lesion, the miliary fungal granuloma, was produced. This lesion was larger and took longer to resolve than the lesion produced by dust alone There was no evidence of invasion of the lung by fungi in those animals which had been exposed to candida But this explanation is by no means established

A LIVELY SOCIETY

It is often said that the general practitioner and the consultant do not see enough of each other they regularly read each other's letters but they rarely meet And if, as another saying puts it, the art of letter-writing went out with the quill pen, it is not surprising that there is, on both sides a wish for closer contact to colour these formal exchanges The gap is being closed in several ways and one of the strongest bridges is formed by the clinical society, whose meetings draw together general practitioners and hospital staff in a very helpful way—helpful to both doctor and patient Though the plan is excellent, it must be backed by much administrative care and dexterity if it is to succeed For one thing general practitioners are not as a rule enthusiastic over meetings of any kind, in the past few years important issues of medical politics have taken them to many more than usual, and some no doubt feel that, though clinical meetings are just the thing once in a while, a monthly meeting is a little too much for a crowded calendar A great deal therefore depends on the attractiveness of what a particular society can offer and hence on the ingenuity of its officers, themselves busy doctors for whom these extra duties reduce already meagre leisure hours

In this respect a clinical society which we saw at this bridge-building last week has been splendidly served by its architects For 64 years the doctors of Ipswich and thereabouts have had their clinical society as a convenient and agreeable means of telling each other about their interesting professional experiences. Like many good things, the Ipswich and District Clinical Society was subdued by the late war, but happily a prompt postwar resuscitation by the then secretary, Mr. F. R Stansfield, obstetrician and gynæcologist to the Ipswich group, soon restored its vigour, and today it is as lively as ever. The society's members include most of the doctors and many of the dentists in East Suffolk, and this year the president is a dental surgeon, Mr. J C. Rowbotham On the average, rather more than half the members attend each meeting On May 2 a new idea, admirably put into execution by the present secretary, Dr R M Mayon-White, pædiatrician in the Ipswich area, turned out to be a winner The society invited the section of general practice of the Royal Society of Medicine down for the weekend The main purpose of the invitation was to encourage doctors from other districts to talk shop in Ipswich homes, but the quality of the afternoon's clinical demonstrations and short papers (four by general practitioners), which formed the introduction to this hospitable plan, was more than enough to make a notable day for those visitors who were unable to stay as long as they wished Dr Mayon-White and his colleagues had fewer patients in groups II and III than in group I is that chloramphenicol was scarce and large quantities were required for treatment in the last two groups.

[5] Zettergren, L *Uppsala LäkFören Förh* 1950 55 257

These findings confirm those obtained in the previous series (El Ramli 1950), when the relapse-rate was less in cases treated for 11–15 days in convalescence (7·7% in 26 cases).

Chloramphenicol of Different Makes

Owing to the increasing number of pharmaceutical firms synthesising chloramphenicol, I felt it necessary to assess the relative therapeutic values of the different makes in typhoid and paratyphoid fever. The results recorded in tables II and III show no significant difference in their therapeutic values.

Rectal Chloramphenicol

Rectal administration is useful in infants and young children, patients vomiting or unable to swallow, and patients unable to coöperate. Chloramphenicol suppositories were used in 22 cases of typhoid or paratyphoid fever, and the response in these cases was identical with the classical response of enteric fever to chloramphenicol (see table IV), the average duration of fever after the start of treatment being 2·8 days. The daily dosage was 50 mg. per kg. divided into two, three, or four doses. This high dosage was instituted because it was my first experience with rectal chloramphenicol, and I thought that absorption through the rectum might be less than after oral administration.

A. W. El Borolossy estimated serum-chloramphenicol levels after the rectal administration of 25 and 17 mg. per kg. and reports his results in an accompanying paper (El Borolossy 1953). With both doses he could detect chloramphenicol in the serum twelve hours after its rectal administration. This result is in accordance with the clinical response obtained and encourages the trial of small dosage of rectal chloramphenicol.

TABLE IV—RESULTS OF TREATMENT OF ENTERIC FEVER WITH RECTAL CHLORAMPHENICOL 50 MG. PER KG. OF BODY-WEIGHT GIVEN IN TWO, THREE, OR FOUR DOSES

Age-group (yr.)	No. of cases	Average duration of fever (days)		No. of relapses
		Before treatment	After treatment	
0–5	12	16·8	2·8	2
6–10	3	9·3	3·3	0
11–15	1	14·0	2·0	0
More than 15	6	11·2	3·2	0
Total ..	22	14·1	2·8	2

16 cases were treated with synthomycetin suppositories and 6 with kemecetin suppositories; there was no difference in response between the two groups.

SUMMARY

398 cases of typhoid or paratyphoid fever were treated with chloramphenicol produced by different firms, and the results were analysed.

The dose used was 12·5 mg. per kg. body-weight twelve-hourly.

The relapse-rate was reduced when treatment was continued for twelve days after the temperature became normal.

22 cases were treated with chloramphenicol suppositories in daily dosage of 50 mg. per kg. divided into two, three, or four doses. The clinical response was the same as to oral chloramphenicol.

I am very grateful to my colleagues Dr. A. Hamid Omar and Dr. A. W. El Borolossy for their unfailing efforts and enthusiasm in this work and for help in the preparation of this paper.

CHLORAMPHENICOL LEVELS IN SERUM AFTER RECTAL ADMINISTRATION

A. W. El Borolossy
Ph.D.
SENIOR LECTURER IN PHARMACOLOGY, ABBASSIA FACULTY OF MEDICINE, CAIRO

Chloramphenicol is effective when given by mouth; but oral administration is sometimes difficult or even impossible—e.g., in cases of coma, persistent vomiting, or mental confusion. Rectal administration, in the form of suppositories, suggests itself as an alternative, and the clinical findings of El Ramli (1953) suggest that, given by this route, the antibiotic attains therapeutic levels in the blood.

TABLE I—SERUM-CHLORAMPHENICOL LEVELS AFTER RECTAL ADMINISTRATION OF 25 MG. PER KG. BODY-WEIGHT

Case no.	Serum-chloramphenicol (µg. per ml.)						
	1st hour	2nd hour	4th hour	8th hour	12th hour	18th hour	24th hour
1	10	20	20	20	10	...	...
2	40	20	30	40	40	...	...
3	20	20	40	40	40	...	...
4				40	20	...	...
5	80	80	40	20		...	...

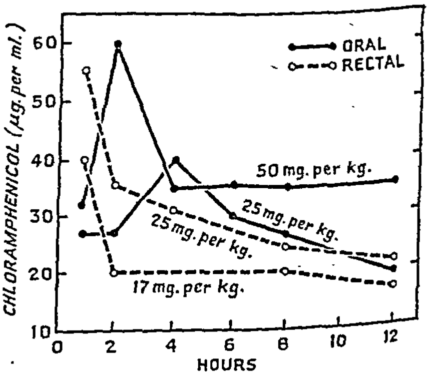
7		40		30		...	...
8	60	20	20	—	—	...	...
9	80	40	30	40	20	...	...
10	80			40		...	...
11		20		20	20	—	—
12		20		10	20	—	—
13				20	—	—	—
Mean	56	36	31	26	21	—	—

... = No sample available. — = Non-inhibitory concentrations.

To confirm this, I estimated the serum-chloramphenicol after rectal doses of 25 and of 17 mg. per kg. body-weight. The sera were obtained from typhoid cases treated at the Abbassia Fever Hospital by Dr. A. H. El Ramli. For the assay of the antibiotic, the turbidimetric method was used, employing a sensitive strain of *Bacterium coli* as the test organism.

RESULTS

Table I and the figure show that a high concentration (average 56 µg. per ml.) was obtained one hour after the rectal administration of 25 mg. per kg. This rapidly declined during the second hour, but was then maintained at an almost constant, moderately high level (between 36 and 26 µg.) between the second and eighth hours. Twelve hours after administration there was still an average concentration of 21 µg. per ml. which in most cases will inhibit enteric organisms. Only in 2 out of 13 cases were inhibitory concentrations not obtained at the twelfth hour. The last 3 samples (table I, nos. 11–13) were examined for antibiotic concentrations eighteen and twenty-four hours after administration; but inhibitory serum concentrations were not found at that time.



Serum-chloramphenicol levels after oral or rectal administration (mean of readings obtained).

assembled at the East Suffolk and Ipswich Hospital a splendid collection of pædiatric cases, medical, surgical, and orthopædic As a visitor remarked, the presentation was up to the best teaching hospital standards The welcome opportunity for an exchange of views and the interest of this model meeting were an example of a combination which we commend to other societies who would like to travel The practice of medicine, and especially general practice, has a habit of taking up weekends and interfering with excursions of this kind, but Ipswich's clinical society has shown that there are considerable advantages in resisting such interference

RECTAL ABSORPTION OF CHLORAMPHENICOL

IN this issue Dr El Ramli, of Cairo, describes the treatment of typhoid and paratyphoid fevers with chloramphenicol, which he administered rectally to some of the patients The antibiotic was given by this route to infants, young children, patients who were vomiting or unable to swallow, and those who were uncooperative The dosage was 50 mg per kg body-weight daily, divided into two, three, or four doses According to El Ramli, chloramphenicol was as effective when given rectally as when given orally, the average duration of fever with administration by either route was about 3 days Dr El Borolossy, also working in Cairo, examined the blood levels of chloramphenicol 12 hours after rectal administration of the drug He states that with a dose of 25 mg per kg body-weight the serum chloramphenicol level reached a high level within an hour and then declined rapidly in the 2nd to the 4th hours Between the 4th and 12th hours the serum chloramphenicol curves after rectal and after oral administration were close together According to El Borolossy, concentrations inhibitory to susceptible organisms were obtained in the serum up to 12 hours after oral or rectal administration of 17–25 mg of chloramphenicol per kg body-weight

These observations do not agree with those of Roy and his colleagues,[1] of Toronto These workers administered perforated capsules of chloramphenicol rectally to convalescent infants and children In some cases the capsules were not retained, but when they were retained the blood levels were disappointing With doses of 55 mg per kg body-weight the absorption of the antibiotic was irregular, and sometimes none could be detected in the serum 4 hours after administration, and even when it was given 4-hourly, the blood levels did not rise above 7 μg per ml After oral administration the blood levels ranged from 10 to 420 μg per ml The rectal dosage, already large, could not be increased, owing to the difficulty of retention Because rectal absorption was so irregular and produced such low levels, Roy and his colleagues concluded that this method of administration is of dubious value Kelly et al,[2] of Philadelphia, report similar experiences They found that the blood level after rectal administration was only about a fifth of that after oral administration of the same dose (22–24 mg per kg body-weight) The blood levels were more consistent after oral administration Absorption from the rectum appeared to take longer than absorption from the upper part of the gut, after rectal administration there was little change in the blood level for as long as 6 hours

Thus it seems that there is little to recommend the rectal use of chloramphenicol Absorption is uncertain, a larger dose of this expensive drug is needed, and possibly proctitis and perineal dermatitis may result If for any reason the antibiotic cannot be given by mouth, it can be administered by intramuscular injection dissolved in acetyl dimethylamine

COMMITTEE ON N H S COSTS

Mr Iain Macleod has now chosen the people who are to meet under the chairmanship of Mr C W Guillebaud, the Cambridge economist,

> "to review the present and prospective cost of the National Health Service, to suggest means whether by modification in organisation or otherwise, of ensuring the most effective control and efficient use of such Exchequer funds as may be made available, to advise how, in view of the burdens on the Exchequer, a rising charge upon it can be avoided, while providing for the maintenance of an adequate Service, and to make recommendations"

Invitations to serve on the committee have been accepted by Mr J W Cook, D SC, F R S, regius professor of chemistry in the University of Glasgow, Sir Geoffrey Vickers, V C, a member of the National Coal Board and of the Medical Research Council, and Sir John Maude, secretary to the Ministry of Health from 1940 to 1945 and later deputy chairman of the Local Government Boundary Commission Mr Macleod also invited the Trades Union Congress to nominate a member, and the T U C have chosen Miss B A Godwin, a member of their council and assistant general secretary of the Clerical and Administrative Workers Union

FOOD-POISONING DUE TO CLOSTRIDIUM WELCHII

BACTERIAL food-poisoning may arise by multiplication of bacteria—usually of the salmonella group—in the intestine, or by ingestion of toxic bacterial products, such as those produced by certain staphylococci Among the organisms which have been suspected, but not convicted, of causing food poisoning is *Clostridium welchii* This was isolated from the fæces of patients in outbreaks described by Klein[1] Many years later McClung[2] described three outbreaks in which *Cl welchii* was isolated from the food, and a volunteer who ate a sample of the food contaminated with this organism developed typical symptoms The important study by Hobbs et al[3] makes it clear that we must now include *Cl welchii* among the proven causes of food poisoning

The outbreaks studied by Hobbs and by previous workers have shown that the usual foods infected with this organism are dishes containing meat which has been cooked, allowed to cool, then eaten either cold or reheated on the following day Stewed, braised, or boiled meats are particularly liable to cause the disease The clinical picture is fairly definite Diarrhœa and abdominal pain begin after an incubation period of 8–20 hours, the patient rarely complains of nausea and vomiting, in contrast with staphylococcal food-poisoning Salmonella food-poisoning almost invariably produces a rise in temperature, whereas *Cl welchii* never causes pyrexia The disease is usually mild, with recovery in about 24 hours, but some old people have succumbed to it

The *Cl welchii* responsible for this disorder shows certain peculiarities On primary isolation the colony is small and is non-hæmolytic, though faint hæmolysis may develop after some days' incubation The organisms are relatively heat-resistant, the spores have withstood boiling in foods for 2–3 hours, and in laboratory experiments for 5 hours Experimental work by Oakley and Warrack[4] has shown that these heat resistant strains of *Cl welchii* produce only small amounts of the recognised clostridial toxins, and these workers believe that the strains should be classified as heat resistant strains of *Cl welchii* type A The organism can be isolated from the fæces of most of the patients affected Hobbs

g constantly found. Nucleated red cells were numerous
r the hæmorrhages.

'ecropsy showed bone-marrow hyperplastic with very
ıerous megakaryocytes, some with ingested cells; the
en with myeloid metaplasia, megakaryocytes not con-
ıuous, some fibrosis, and malpighian bodies few and
ıll; and the liver with very slight myeloid metaplasia.

'ase 8.—A man, aged 51, died in July, 1950, of weakness
ı wasting, after four a half years' observation. The
senting symptom was intestinal hæmorrhage in March,
6, when a large spleen was found. The first intestinal
morrhage took place in 1942, and these were repeated until
8. The patient was subject to abnormal bruising in 1949
l 1950. He had no polycythæmia while under observation,
any history suggesting it. He had never had severe
emia except after intestinal hæmorrhages. His leucocytes
re normal in 1946–48 but later increased to 20,000 per
m., and in 1949–50 he had leucopenia. Immature
cocytes were 8–12% before the first course of X-ray treat-
nt in November and December, 1948, which improved his
alth considerably. A second course, in 1949, also had a
od effect, but a third course, in 1950, had no effect. The
tient had gout in his great toes in 1948–49. His serum-
ic-acid level was 6·6–8·3 mg. per 100 ml. in 1948–50.

Necropsy showed fibrosis throughout all parts of the bone-
arrow examined, very dense in places; but in most areas
e bone-marrow cells, especially the megakaryocytes, were
cognisable; the spleen with myeloid metaplasia and very
ıall and scanty malpighian bodies; and the liver with very
ght myeloid metaplasia only.

Case 9.—A woman, aged 74, died in January, 1946, of
art-failure, after six and three-quarters years' observation.
ıe presenting symptoms were diarrhœa and the passage of
ood per rectum in April, 1939, when a large spleen and a
ge liver were found. The patient was subject to abnormal
uising from 1937 onwards. She had "chlorotic poly-
thæmia" in 1939, with more than 7,000,000 red cells per
nm., but her Hb was 70%. After having iron by mouth she
veloped typical polycythæmia, which later disappeared.
ıe had high leucocytosis (40,000–60,000 per c.mm. with
ss than 1% immature leucocytes); later the number
leucocytes became normal, but a few immature leucocytes
rsisted. The patient had gout in her hands and feet in
40–41. Her blood-uric-acid level was above 7 mg. per
0 ml. in 1939–41. She died of congestive heart-failure.
o necropsy was done.

DISCUSSION

Gout occurs fairly often in patients who have myeloid
ıetaplasia involving all three main bone-marrow
ements—erythroblasts, leucoblasts, and especially mega-
aryocytes—but it does not occur commonly in patients
ho have mainly leucoblastic myeloid metaplasia or
ıainly erythroblastic myeloid metaplasia. The blood-
ric-acid level is usually normal in typical cases of
rimary polycythæmia (Wintrobe 1951), and most cases
f typical chronic myeloid leukæmia under my care
ave had a normal blood-uric-acid level. The most
triking fact is that myeloid metaplasia occurs in some
atients who have had gout for many years, and this
ıust be of great importance in considering the causes of
ıyeloid metaplasia, and may throw light on the cause of
hronic myeloid leukæmia. In most of the published
ases in which gout occurred years before the myeloid
plenomegaly was discovered there is no means of knowing
hen the disorder of the blood-forming tissues began;
ut 1 patient was seen with gout three years before
plenomegaly was found (Coste et al. 1948). In the type
f case under discussion gout may occur more commonly
han is generally believed, for the descriptions of several
atients suggest that they had gout, though not diagnosed
s such (Rosenthal and Bassen 1938, Vaughan and
Harrison 1939, Dustin 1947).

Several other patients under my care, with "megakaryo-
ytic myelosis" or "myelosclerosis," had constantly high
lood-uric-acid levels, though they did not develop gout.

Rarely gout may occur in acute myeloid leukæmia;
and a patient with chronic gout may have an acute fatal
illness closely simulating acute myeloid leukæmia.

SUMMARY

The relationships between gout, myeloid leukæmia, and primary polycythæmia are stated.

Gout occurs much more commonly in patients with myeloid metaplasia involving erythroblasts, leucoblasts and megakaryocytes than in patients with typical myeloid leukæmia or with typical primary polycythæmia.

SUPPORTIVE THERAPY

AN IMPROVED TYPE OF DEXTRAN

INTENSIVE investigation into the causes, prevention, and treatment of shock was made necessary by two wars. But in a world of increasing mechanisation, with its heavy toll of accidents, shock is far from being a purely war-time problem. Collaborative research has resulted in a clearer understanding of supportive therapy, and the importance of maintaining the circulating blood volume has been firmly established. The wide use of blood-transfusion and plasma infusion means that surgical shock, as formerly known, is no longer seen.

The expense and potential shortage of stored blood and the danger of virus hepatitis after infusion of plasma have stimulated a revival of the search for alternative substances for supportive therapy. These substances have been termed "plasma substitutes," but with the development of materials which in many respects are preferable to plasma it is felt that a new designation is required. Since the primary use of these substances is to restore or to maintain the circulating blood volume, the term "blood-volume restorer" is suggested.

CRITERIA FOR BLOOD-VOLUME RESTORERS

Ease of infusion.—The viscosity of the material should be such that it is easily infusable in all climates.

Freedom from undesirable effects.—The substance must not be toxic or antigenic. It must not produce hæmolysis. It must be easily sterilisable and free from pyrogens.

Maintenance of manufacturing standards.—The material must be capable of rapid and economic manufacture on a large scale, with exactly reproducible composition. It must be storable, without alteration, for long periods under varying conditions of temperature.

Elimination from the body—The material should eventually be excreted or metabolised Any storage in the body should be brief, and there should be no adverse effect, either immediate or delayed, on any organs or at the site of injection

Retention in circulation—A satisfactory blood-volume restorer should remain in the blood-stream with levels of not less than 50% of the amount infused at the end of twenty-four hours This implies that the material should not be rapidly katabolised, excreted, or readily diffusible through the capillary wall The retained material must also have an adequate water-holding capacity

The mechanism by which macromolecular colloids hold water in the circulation is complex There are two main factors involved (1) the osmotic pressure of the solution, which depends on the molecular concentration and hence decreases with increase in molecular weight, and (2) the water-binding capacity of the colloid, which increases with increase in molecular weight The combined effect of these two factors, which tend to balance one another may be termed the water-holding capacity of the colloid

TYPES OF MATERIAL

During the last few years interest has been focused on three polymers polygelatin, polyvinylpyrrolidone, and dextran Because these substances are polymers they can be produced in various ranges of molecular size, and it is possible to obtain samples of the same polymer having widely differing properties It is shown below that molecular size is of the utmost importance

In the form which has been used for infusion gelatin produces a highly viscous solution which does not flow easily at room-temperature in this country In our experience it is necessary to warm this material before infusion Injudicious heating may cause denaturation, this may also happen with prolonged storage Evidence has also been produced of tissue changes after the infusion of gelatin (Skinsnes 1947) A derivative, oxypolygelatin, has been produced which is less viscous in solution and stable to storage The advantage, however, has only been achieved at the expense of a high excretion-rate and a correspondingly low blood level

Polyvinylpyrrolidone cannot be broken down in the body and tends to be accumulated in the liver and reticulo-endothelial system (Nelson and Lusky 1951) The German army used a form of polyvinylpyrrolidone during the war 1939–45, and Müller (1946) reported that the appearance of the spleen and lymph-nodes at necropsy after the infusion of this material was comparable to that seen in the storage diseases The use of the material was given up after army pathologists had found widespread liver and kidney damage More recently a type of polyvinylpyrrolidone has been prepared with a much smaller molecular size than that used by the Germans It is claimed that this does not give rise to organic changes, but the excretion-rate is so high that the effect on the circulation volume can only be transient

Dextran, which is a polymerised form of glucose, does not seem to be stored in the body in significant amounts, and is probably eliminated by being broken down to a molecular size small enough to be excreted by the kidneys, or glucose elements may be broken off and utilised as such A few reactions of an anaphylactic type were reported with some of the earlier kinds of dextran, these were considered to be due to the presence of large molecules, but the possibility of contamination cannot be completely excluded More complete hydrolysis of the crude dextran produced a material virtually free from reactions but at the cost of a high excretion-rate and a low twenty-four-hour blood level

Because of its basic advantages it was decided to investigate the possibility of preparing an effective blood-volume restorer from dextran The problem was to determine the best molecular range and to find out if the material could be produced on an economic scale

DETERMINATION OF BEST MOLECULAR RANGE

Dextran is prepared biosynthetically from sucrose by t action of *Leuconostoc mesenteroides*, which polymeris the glucose half of the molecule Before it can be us the crude dextran must be hydrolysed, the result product containing molecules of molecular weight rang from a few thousand to several million in a proporti depending on the time and conditions of hydrolysis.

From a physiological point of view the molecul spectrum may be divided *arbitrarily into four range*

(1) The highest range consists of those molecules wh are so large that they may produce undesirable reactions

(2) The lowest range consists of those molecules which p through the glomeruli and are excreted

(3) Above this is the range of molecules which are to large to be excreted but small enough to diffuse through th capillary wall and thus be lost from the circulation into th tissue fluid *These molecules are undesirable because, apa from any effect on the intracellular-extracellular fluid balanc they have a certain water-holding capacity, and this associate water is lost from the circulation*

(4) The next highest range contains those molecules whi are too large to diffuse through the capillary wall but n large enough to produce reactions

It therefore seems logical that the ideal form *dextran should be that containing the largest amou* possible in the last-mentioned range

To estimate the transition values between the vario ranges it was necessary to obtain a distribution curve the molecular spectrum for each of the types of dextra involved *This was done by obtaining samples of a ve* small part of each range by repeated fractionation from suitable solvent, and by measuring the intrinsic viscosit of each sample For the sake of clarity the charac teristics of each type of dextran used are described he *in terms of molecular weight* Since the values of th molecular weight have been derived from intrin viscosity measurements, the figures given must b regarded as approximations until they can be confirme by ultracentrifuge studies on the type of dextran use

From studies of excretion rate and blood levels in th rabbit and man with various types of dextran, describe in more detail below, the glomerular threshold seems t correspond to a molecular weight of 60,000, and th capillary threshold appears to be about 130,000 in ma and a little higher in the rabbit It must be borne i mind, if tempted to compare these figures with that o albumin, that diffusion depends on other factors beside molecular weight—e g, charge and shape It is impractic able to produce anaphylaxis in man and it was impossib to demonstrate it in the rabbit with any form of hydr lysed dextran free from pyrogens and other contaminant It is therefore thought that an upper limit at a molecul weight of 250,000 leaves an adequate margin of safety

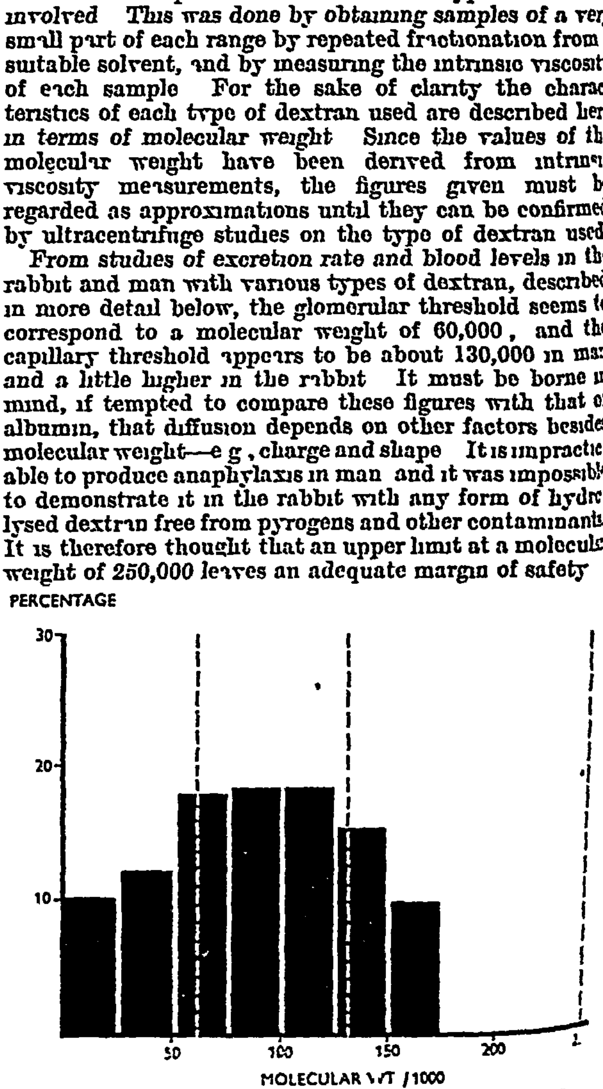

Fig 1—Distribution of molecular weight of standard dextran

isolated them from 89·9% of these patients, but from only 2·2% of normal persons. In a study of animal fæces the organism was rarely isolated from bovines but not uncommonly from pigs, rats, and mice. It was also isolated from fresh meat (except lamb) and from blowflies. Volunteers developed mild food-poisoning after eating cultures of *Cl. welchii* which had been isolated from contaminated meat, but it was uncertain whether the disease was due to a toxin alone, or to the ingestion of vegetative organisms.

There seems little doubt that this type of food-poisoning, like others, could be eliminated by good hygiene. Once more the dangers of eating precooked foods, kept a long time in conditions suitable for bacterial multiplication, have been demonstrated.

TEN NUFFIELD YEARS

TEN years ago Lord Nuffield, having set up and munificently endowed the foundation which bears his name, charged it with the task of advancing health and social well-being. Its work is thus one in which we should all like to take a hand and an interest. In its progress report[1] the foundation describes itself as "a private fund serving the community," and it has certainly made good use of the opportunities offered by its amateur status. As a discerning pioneer it has been quick to foster schemes likely to be of public benefit but not yet sufficiently established to have won official support, and it has generously backed workers engaged in promising but admittedly speculative research.

Over the ten years, 1943–53, the foundation's total income has been £5¼ million, of which it has spent nearly £4¼ million. £786,000 has been given to medical work (including £229,000 for rheumatism); £347,000 to biological research; £560,000 to research in physics; £463,000 to the social sciences; £32,000 to agriculture; £925,000 to the care of old people; and £831,000 to fellowships and scholarships.

During the second half of the period the emphasis of the programmes for medical work shifted from particular specific diseases (with the exception of rheumatism) to normal health. Thus it has made grants of £167,220 to promote teaching and research in child health. The largest grant (£100,000) was spent on the establishment of an institute of child health in the University of London. Industrial health has also claimed its support, and £150,000 was given to establish departments of industrial health in the universities of Durham, Glasgow, and Manchester, and over £15,000 to set up a working model for an industrial health service on the Slough trading-estate. Disquieted by the Teviot report on the unsatisfactory state of the nation's teeth, the foundation also decided to encourage postgraduate teaching and research in dental health, and it has made grants totalling £90,000 to the dental schools in the universities of Durham, Leeds, and Manchester and at Guy's Hospital.

The chronic rheumatic diseases cost the community so dearly in health and distress that the foundation felt justified in singling out this group of diseases for special attention. Accordingly in 1947 it financed a pioneer centre at Manchester for the study of rheumatic diseases. The following year the management of the Oliver Bird Fund of £450,000 for the study and alleviation of rheumatism was entrusted to the foundation. Since 1947 it has financed much chemical work aimed at the total synthesis of cortisone and corticotropin (A.C.T.H.). The foundation's keen eye for the future has also ranged purposefully over the biological sciences, and its eclectic help has been offered to workers studying such diverse topics as cellular biology, micro-organisms, comparative endocrinology, immunology, and neurophysiology. A second part of the report, which is to appear shortly, will describe the allocation of grants and fellowships in more detail.

THE SMALL-LIST DOCTOR

DISSATISFIED with the prospects for the small-list general practitioner under the distribution scheme which came into operation on April 1, a group of members of the British Medical Association made requisition in March for an extraordinary general meeting of the association; and this meeting was held on May 5. The resolution before the meeting was:

> That the Association being concerned by the modification of the present method of remuneration by capitation fees agreed in the Working Party's report requires the Council forthwith to approach the Minister of Health with proposals for the better protection (financial and otherwise) of the small-list doctor and of the doctor newly seeking entry into practice, and requests the Minister of Health not to implement the Working Party's report until the scheme for distribution of remuneration has been considered in the light of such proposals, and meanwhile to continue the present method of payment.

In proposing this resolution, Dr. W. J. Grant claimed that for the small-list man and the newly entered practitioner the Working Party's distribution scheme was tantamount to direction of labour by economic pressure—a device which no Government would have dreamed of using against the humblest member of a trade union. A practitioner's inescapable expenses were identical whether his list was 500 or 1500; and in Dr. Grant's view the present scheme paid little regard to this fact. He suggested loading the capitation fee for the first 1500 patients—say, 8s. a head for the first 500 and 6s. for the next 1000—as a means of remedying this "inexcusable injustice."

The chairman of the General Medical Services Committee, Dr. A. Talbot Rogers, explained that his committee had found it impossible to propose an immediate plan to offset the difficulties of the small practice, because they would know neither the size of the problem nor the amount of money available to solve it until the effects of the new distribution scheme had been observed. It was simple enough to find out which doctors had small lists, but the reasons for the small lists were much more complicated. To enable the facts to be collected and the results of the new scheme to be analysed, the Working Party had been recalled and had already begun its discussions. Preliminary figures for March and April indicated that the number of principals in general practice was increasing in the way that the Working Party had hoped, and that the consequent gain to the central pool would be more than enough to provide for cases of hardship among small-list and newly established practitioners. Dr. Talbot Rogers thought that hardship was not so widespread as many people believed, but he assured the meeting that now the necessary information was becoming available a satisfactory answer would be found. The meeting readily accepted this assurance and confirmed by a very large majority the approval given to the Working Party's plan by the association's Representative Body in Dublin last July.

It is easy to understand the impatience of those doctors who may be in real difficulties under the new method of distribution; but it is equally clear that any changes based on uncertain evidence would lead only to further dissatisfaction. At all events, the meeting made it clear that these difficulties are certainly being tackled—and in a sensible way—which is no doubt what those who asked for the meeting wanted to know.

Sir ROBERT ARCHIBALD, professor of bacteriology and parasitology in the Farouk University, Alexandria, and a former director of Wellcome Tropical Research Laboratory in Khartoum and the Stack Medical Laboratory, died on May 2 at the age of 73.

The suggestion of Dr Frankel and Dr Ellis Moore (April 18) that pancreatic enzyme action is deficient because of the rapid passage of food in the bowel is interesting. One of the investigators in this department has shown[1] that in dogs the external pancreatic secretion in response to a meal is markedly reduced after gastrectomy. This may be an additional factor in the deficiency syndrome. In the four cases I have described, however, no improvement has been observed after giving sodium bicarbonate by mouth. In three of the cases, a reduction in the severity of the deficiency symptoms has been noted after supplying pancreatic enzymes in addition to alkali, but in none has the griping abdominal pain been relieved.

IAN MACPHEE

INFLUENCE OF LANGUAGE ON MEDICINE

SIR,—In his letter published in your issue of April 11, Dr Penman inquires whether any of your readers knows who adopted the motto *Nullius in verba* for the Royal Society. John Evelyn proposed this motto among several others, but Dr Penman might like to read pp. 142–144 in volume 1 of *A History of the Royal Society* by C. R. Weld (London, 1848).

The Royal Society,
Burlington House,
London, W. 1

D. C. MARTIN
Assistant secretary

HAZARDS OF LUMBAR PUNCTURE

SIR,—In your leading article of April 11 you say that "the occurrence of headaches in 40% of ambulant patients in Sciarra's series confirms the idea that twenty-four hours' rest in bed is advisable after lumbar puncture." If this suggestion is accepted, it follows that every patient who is to have lumbar puncture must be admitted to hospital. Even if this were practicable, the necessity for it would be debatable. The experience of Williams[2] in military hospitals suggested that headache was commoner among patients who were confined to bed after lumbar puncture than among those who were returned to duty.

In a clinic such as this, where many cases of syphilis are investigated and treated, lumbar puncture is a routine procedure. The number of patients involved is such that, if they were all to be admitted, the delays would be considerable. Most of them are working men and women who are free from symptoms and many would strongly object to the idea of entering hospital, either because to do so would be inconvenient or, in some cases, because it would involve disclosure of some of the facts of their illness to relatives and friends. In these circumstances it is more satisfactory to perform routine lumbar punctures in the outpatient department, and to allow patients to return to their homes or their work immediately afterwards. To do so has been the practice in this clinic for some years. Arrangements for admission to hospital are made only for elderly patients, for pregnant women, or for patients with some serious disability.

Recently during an investigation undertaken to assess the value of the Dattner needle in reducing the incidence of headache following lumbar puncture, we made a survey of the case records of 258 patients (168 male and 90 female). All of these had lumbar puncture performed in the outpatient department, and were then allowed to return to their ordinary occupations. At the next visit they were asked whether they had noticed any reactions, and if so, what was the nature, duration, and severity of their symptoms. Many who had suffered slight or moderate symptoms made no spontaneous complaint. The frequency and severity of symptoms were as follows:

54 patients (21%) complained of severe headache, 28 (11%) of moderate headache, and 36 (14%) of mild headache.

22 patients (9%) had noticed some stiffness or soreness of the back.

118 patients (46%) had noticed no ill effects.

In assessing the results it can be seen that 118 patients (46%) had had some degree of headache, but in many cases this had been so mild and transient as to cause them little or no inconvenience. Of the 54 patients (21%) who complained of severe headache, the majority recovered completely after a few days' rest in bed with no special treatment.

In the absence of any conclusive evidence that enforced rest in bed for twenty-four hours will appreciably reduce the risk of severe headache, we submit that the practice of performing lumbar puncture on ambulant patients is justifiable. It seems hardly necessary to add that in these, as in any, circumstances lumbar puncture should be carried out with strict aseptic precautions and all possible care and skill.

Whitechapel Clinic,
London Hospital, E. 1

E. GALLAGHER
C. G. H. CAMPBELL

SIR,—May I support most strongly the remarks by Dr Jackson (April 25) regarding general anæsthesia during pneumo encephalography.

Though it may be said that general anæsthesia adds another risk to a procedure itself not free from hazard, the advantages of its use in children, or even in an adult if one has reason to believe he will coöperate badly, to my mind far outweigh this risk. It is kinder to the child; vomiting does not occur; the required position is more easily maintained; better films are obtained; and the procedure is accelerated. In addition, as Dr Jackson says, both in children and in adults there is a striking reduction in the subsequent headache and vomiting.[1]

This is not easy to explain, however; for the degree of meningeal irritation, as shown by the polymorphonuclear pleocytosis in the cerebrospinal fluid is the same with or without anæsthesia. It is not due to prolonged unconsciousness, for the patients have usually come round by the time they return to the ward. Whatever may be the reason for this difference, so striking is it that patients who have been unfortunate enough to have to undergo this unpleasant but valuable procedure twice, and who have experienced both methods, leave no doubt in the minds of their doctors and their fellow patients which they prefer.

Birmingham

EDWIN R. BICKERSTAFF

TRAINING OF PHYSIOTHERAPISTS

SIR,—Dr Cawadias, in your last issue, expresses himself as being at a loss to understand the tendency of the Chartered Society of Physiotherapy to monopolise physical treatment in this country. As one who has availed himself a great deal of the help of its members the answer seems to me plain.

This body was formed nearly sixty years ago, its members pledging themselves (unasked) to work only under medical direction. Their three-year course of training is at officially recognised schools, usually associated with teaching hospitals. By 1920 their status was such that a Royal Charter was conferred upon them, and Queen Mary became their Patron. In this way their members have become, in Dr. Cawadias's words, "accepted members of a medical team, receiving alike the support of the medical profession and the confidence of the public."

The Government-sponsored Cope Committee which reported last year, after examining all the available evidence, stated that the Chartered Society of Physiotherapy's standard of training appeared to be the only one acceptable for universal adoption in the National Health Service. It has surprised many that this report

Special Articles

CONFERENCE ON POLIOMYELITIS

A MEETING, under the chairmanship of Sir JOHN CHARLES, the chief medical officer, was held at the Ministry of Health on April 15, to discuss the implications of the recent Danish outbreak of poliomyelitis in which there were a large number of cases with respiratory paralysis of the bulbar and bulbospinal forms for which an unusual method for maintaining respiration was adopted. This method, which has been described by Lassen,[1] consists in the performance of a tracheotomy and insertion of a cuffed endotracheal tube; through this tube intermittent positive-pressure ventilation with a nitrogen-oxygen mixture is maintained by means of manual compression of a rubber bag.

The meeting was attended by representatives, including specialists in infectious diseases and anæsthetists, from all regions and was addressed by Dr. W. H. Kelleher, Dr. B. A. Sellick, Dr. A. B. Christie, Dr. J. R. Esplen, and Dr. G. E. Breen, all of whom had visited the Blegdams Hospital, Copenhagen, where they had seen this method of treatment employed.

Dr. KELLEHER said he had reached the conclusion that Lassen's method should be studied carefully and, perhaps with certain modifications, should be used for suitable cases in this country. The Danes had found that in certain bulbar forms of poliomyelitis treatment by postural drainage alone was not always enough; and their method, which aims at the clearance of the upper air-passages and prevention of flow of secretions into the lower air-passages, is claimed to have brought about a considerable fall in the mortality. As regards points of detail, Dr. Kelleher questioned the need for a closed-circuit apparatus with the danger of inhalation of soda-lime particles; he also thought that consideration should be given to the use of silver tubes wherever possible in place of rubber tubes, with a view to minimising the risk of producing stenosis of the trachea.

Dr. SELLICK said he felt that in this country we should concentrate on the good points of Lassen's method but consider whether any improvements are desirable. He had the impression that more cases than necessary were subjected to tracheotomy and suggested that instead of immediate tracheotomy an endotracheal tube should be passed through the mouth (when the upper air-passages have been cleared) and allowed to remain there for 8–12 hours, during which time the patient's condition could be assessed and the causes of respiratory embarrassment more accurately defined. He mentioned the practice of Nielsen, of Sweden, who leaves an endotracheal tube in place for as long as 3 days in the treatment of barbiturate poisoning (though it is not easy to keep an endotracheal tube in position in a conscious patient). Dr. Sellick wondered why so much stress had been laid on the use of a mixture of 50% oxygen and 50% nitrogen, and thought that at any rate in the more chronic cases mixtures of air and oxygen or compressed air alone should be satisfactory. Dr. Sellick emphasised the importance of *adequate* postural drainage and the value of introducing drugs to prevent bronchospasm and reduce sputum viscosity.

Dr. CHRISTIE and Dr. ESPLEN discussed the types of case for which Lassen's method was suitable. Dr. CHRISTIE pointed out that postural drainage is difficult when the patient is being nursed in a tank respirator but could easily be employed in conjunction with the Copenhagen method. He was impressed by the amount of secretion which could be aspirated through the endotracheal tube in the Copenhagen method. Dr. ESPLEN supported Dr. Sellick's suggestion for the use of an endotracheal tube passed through the mouth for a few hours while the patient's condition is being assessed.

Dr. BREEN, whose visit to Copenhagen was more recent than those of the previous speakers, said that the Danes were now inclined to think that cuffed tubes were not always necessary and that well-fitted silver canulæ were quite satisfactory in some cases. He said that they had completely abandoned the use of tank respirators and were relying on bag ventilation. Dr. Breen suggested that in order to overcome the disadvantages of manual compression consideration should be given to the use of the Bang respirator,[2] the use of compressed air with a Kifa motor, and the Spiropulsator. He said that a Bang respirator could be made for £40–50 and that a spiropulsator costs about £150.

Mr. T. HOLMES SELLORS said that he thought that the chief need in dealing with this problem was proper coördination between the various branches of the profession, and emphasised the valuable part which can be played by anæsthetists with experience in chest surgery. These anæsthetists are skilled at treating "wet lungs," and their services should be employed in the early stages when they could best advise on the method of treatment to be used. Mr. Holmes Sellors thought it was important to avoid unnecessary tracheotomies, and underlined the value of postural drainage when this is properly carried out.

Dr. W. RITCHIE RUSSELL agreed with Mr. Holmes Sellors about the important part which anæsthetists can play, and endorsed his references to the value of adequate postural drainage. In this connection he mentioned the need for the proper training of the nursing staff. He said that pure spinal cases should be treated in tank respirators but that such respirators were not of course suitable for pure pharyngeal cases. For such cases postural drainage was the treatment of choice; tracheotomy had been advocated in the United States but was becoming less common. He was somewhat sceptical about the claims put forward for the Copenhagen method and thought that it was only likely to be useful for combined bulbar and spinal cases.

Mr. TERENCE CAWTHORNE reminded the meeting that tracheotomy can be a mutilating procedure, and when employed should be carried out below the first ring of the trachea so as to avoid the risk of subsequent laryngeal stenosis. He suggested the use of an expiratory valve so as to enable the patient to cough and use his voice; the valve should be removable, to allow aspiration of secretions. Mr. Cawthorne said that tracheotomies should be performed by persons experienced in this procedure; a circular hole was best as it was least likely to give rise to stenosis.

Dr. A. CRAMPTON-SMITH, who referred to his experiences as anæsthetist to a unit for head injuries, described his practice of emptying the stomach and bronchi in patients whose cough reflex has been lost. He referred to the danger of ulceration of the glottis and trachea if endotracheal tubes are left in place for too long. He also referred to a hand inflator, developed by Prof. R. R. Macintosh, which is useful as a pure emergency measure.

Dr. T. D. CULBERT said that he was of opinion that analysis of blood gases frequently gave helpful information in the management of patients being treated by artificial respiration.

Dr. T. ANDERSON, who had also visited Copenhagen, emphasised the value of team-work in dealing with these cases, but said that the team must have a leader. He also referred to the importance of an adequately trained nursing staff.

Dr. E. C. BENN thought it important that a modified tank respirator should be designed to allow the nursing of a patient in the prone position with a view to ensuring adequate postural drainage. Dr. J. G. JOHNSTONE, on of the Cope Committee should apparently have been pigeon-holed, and the reasons for this are a matter of which more should be heard

RENAL DUCTS OF BELLINI

SIR,—I see by Dr Duran-Jorda's letter last week that he is not satisfied with the anatomical and clinical data I presented (April 18) to show that the ducts of Bellini communicate with the renal calyces I hope that some histologist will soon furnish us with an authoritative statement on this subject

Dr Duran-Jorda, referring to comparative anatomy in support of his views, informs us that the kidney of the cat has no Bellini ducts at all Following his example it may be of interest to note that the kidney of the elephant—judging by the specimen in the Royal (Dick) Veterinary College, Edinburgh—has very nice ones

Edinburgh. JAMES A ROSS

HOSPITAL COSTING

SIR,—May I reply to your comment on my letter of April 25?

Your quotation from the Nuffield Trust report on the subject of "dramatic economy" and "dramatic waste" does not by any means convince me that you were right in saying that "it is generally agreed that there is no large-scale extravagance to be exposed" Rather am I confirmed in my previous statement that "no authoritative pronouncement has been made to this effect" and my doubts that the Ministry of Health would subscribe to it Indeed, as previously stated, the Ministry's actions have long indicated entirely opposite views If further support is wanted for my contention about extravagance, it will be found in the report of the Comptroller and Auditor-General on the National Health Service accounts, published only a few days ago The following are only some of the items "Losses of bedding and linen included sums of £6963 and £8150 at two large hospitals" "At some other hospitals it is still not possible to discover the deficiencies" "Farms and gardens run by the hospitals showed a deficit of £614,033 (without taking into account rent and depreciation), as compared with £569,087 in the previous year"

I note that you accept as sound my example, taken at random, of the hopelessness of the alternatives to costing suggested in your annotation of March 28—with the reservation that you had in mind other fields in which financial cost figures may be relatively uninformative compared with staff numbers I think we can rest assured that no administrator would consider cost figures as in a vacuum, whether in providing medical, nursing, or any other services, including catering Cost figures are only a guide—a steady platform from which to survey the field of action and not a diving-board! It may well be that from such a vantage-point it may be useful to count heads, and to allow for those wearing the laurel wreath of a merit award But let the platform first be erected

Moreover one must be selective in the innumerable comparative indices which can be thought up Your reference to a "battery of indices" must surely send a chill through those who by experience know that many a so called index is a misnomer in that it does not point significantly in any direction These words accord ill with the views of modern management, and, indeed, are difficult to relate to the view expressed in your annotation that "the figures which are of most use, to laymen and executive officers alike, are the simplest figures—the figures behind which lies little calculation and 'treatment'"

When you ask in your final sentence "for common-sense adaptations to the special problems, not merely conventional systems applied wholesale," it is obvious that you approve of the systems outlined in the costing reports of the Nuffield Trust and King Edward's Hospital Fund, both of which have taken the most appropriate principles and practice from industrial accounting and adapted them to hospital requirements No-one suggests that a costing system for the production of the "Comet" is suitable for assessing costs incurred in treating a hospital patient, and, conversely, no-one would suggest the use of a hospital system for industrial purposes Nothing conventional will do—industrial systems are tailored to individual requirements, and the conventional method of costing in hospitals is a proved failure But if by a "conventional" system you have in mind to decry a business-like system developed to the point of actual comprehensive usefulness, then I can assure you that "half measures" will only serve to add to the present confusion, no matter how much they are buttressed about by indices

ADMINISTRATOR

SIR,—Nearly seventeen years ago, Dr Andrew Topping drew attention [1] to the futility of attempting to compare maintenance costs in hospitals He wrote "Few, if any, hospitals are exactly alike as regards construction lay-out, type of work done, staffing arrangements, occupation rates, and financial commitments" Those who are now attempting to draw comparisons would do well to read Dr Topping's article

AN UNUSUAL TYPE OF HERNIA

SIR,—The unusual herniæ described by Mr Howard (Feb 21) and by Mr Rose (May 2) seem to be examples of an uncommon type of direct inguinal hernia that I described in 1937 [2] I have since found it perhaps a dozen times, and several of my friends and colleagues have told me that they have encountered instances, but I have *not seen any references to it in the literature*

The hole may be anywhere in the tendinous lower part of the fused internal oblique and transversalis, but I have never seen it as far out as it seems to have been in Mr Howard's case I have always assumed that these herniæ come through congenital defects because the margins of the hole are sharp and tendinous, quite unlike the diffuse bulge of a structure that has yielded to prolonged presures

London, W 1 HENEAGE OGILVIE

SIR,—I have read with interest the case reported by Mr Howard Soon after this account appeared I came across a similar case

A woman, aged 50, was admitted on March 6, complaining of a painful lump in the left groin with pain in the abdomen She had noticed this lump, which she took to be a hernia for the past six months, and was able to reduce it herself Lately it had become more painful, and it had become difficult to reduce it, although she had always succeeded in doing this up to the time of admission During the day of admission she had severe colicky pain in the abdomen, but she did not vomit The lump in the groin was very tender, and the patient could not reduce it She then came to hospital and was admitted At no time could muscular effort be related to the appearance of the lump

The lump was more or less at the site of the left internal ring There was a suspicion that it was slightly higher than one would expect, but because of the patient's obesity it was impossible to ascertain its position accurately

At operation an incision was made parallel to and about 1 in above the left inguinal ligament The external oblique aponeurosis was cut through, and, as in Mr Howard's case, a lump of fat was noticed over the fibres of the internal oblique muscle and apparently attached to it On exploring this lump of fat, which was about 2 in above and lateral to the internal ring, a small hernial sac was found which was about the size of a plum stone It was now empty, the hernia apparently having reduced itself as soon as the general behalf of the Ministry, said that specifications will shortly be circulated for the modification of the Both respirator, but that such modifications will not, for the moment, facilitate the use of postural drainage for patients being nursed in these respirators.

[1] *Lancet* 1936 ii 807

[2] *In* Post-Graduate Surgery, edited by R Maingot London, 1937, vol 3, part 18 chapter 2, p 3620

At the conclusion of the meeting Dr. R. A. **Beaver** demonstrated a machine which he has developed to provide automatic compression and which can be used in conjunction with bag ventilation (the "artificial student"). He said that such a machine could be produced for £16 complete, but that at present it was not possible to purchase the electric motors, as there is a delay of three months in delivery from the manufacturers.

THE WORLD'S FOOD-SUPPLY

On March 25 the food group nutrition panel of the Society of Chemical Industry held the third of a series of four meetings[1] on Food and the Future. On this occasion it considered New Natural Sources of Foodstuffs.

FOOD AND FODDER YEAST

Mr. A. C. **Thaysen**, ph.d. (Colonial Microbiological Research Institute), whose paper was read by Mr. H. J. **Bunker**, pointed out that the value of yeast lies in its ability to convert about 80% of the inorganic nitrogen of the medium into protein. The rate of conversion, compared with more orthodox methods, is enormous. For example, a fully grown bullock, weighing half a ton, produces protein at the rate of 0·9 lb. per day; half a ton of soya bean yields at the rate of 82 lb. per day; while half a ton of torulopsis yields 51 tons of protein in twenty-four hours.

Food yeast is at present being produced both in Jamaica and in South Africa. The cost—at 1*s*. 2*d*. per lb.—corresponds to 0·069*d*. per lb. of protein, compared with 0·8*d*. per lb. of protein from beef. Very little yeast, however, is at present consumed by man. In Germany and Finland it is used solely as animal feed. Compared with other sources of animal feed, yeast is expensive; for it sells at £130 per long ton, compared with soya-bean meal at £30.

Yeast contains an appreciable concentration of vitamins. As a supplement to human dietaries, apart from its protein content, yeast would supply much-needed members of the vitamin-B complex, and used in this way it is certainly economical.

Dr. Thaysen emphasised that yeast is recommended only as a supplement and not as the sole source of protein. Yeast itself is deficient in methionine, and as a sole source of protein would therefore be inadequate; but in combination with other foods which compensate for this deficiency, yeast would be a valuable addition.

He pointed out that the very fact that waste materials were being used as media for growing food yeast was a measure of our shortage of food. Mr. Bunker emphasised the future possibilities of food yeast, when present economics could be considered irrelevant. He pointed out that dried brewer's yeast sells at £90 per ton, and when debittered, but not extracted, at £130.

The value of torulopsis as a food converter, compared with saccharomyces, lies in its ability to ferment pentoses as well as hexoses. This is valid only when waste sulphite liquor is used as a medium: when grown on molasses both these organisms are equally valuable. Vast quantities of raw material are available—for example, as much as a quarter of a million tons of waste sulphite liquor, which really is a waste material, is available annually in the United States and Canada, as well as hydrolysed wood, banana skins, bracken, and peat. *Rhodotorula gracilis* could provide a valuable addition to fat resources, since the organism contains 42% fat and 23% protein.

EFFICIENT USE OF SUNLIGHT

Mr. N. W. **Pirie**, f.r.s. (Rothamsted Experimental Station), outlined the measures generally proposed for increasing the world's food-supply. On the question of increased irrigation, when the water-supply is limited this may involve diverting water from hydro-electric schemes, and the settlement must depend on quantitative considerations. On low-lying land the water can be run through the turbine and then used for irrigation. On high land it is necessary to compare the energy obtained from the water when converted (*a*) via the turbine and (*b*) via the extra plant growth.

As to an increase in cultivable area, this implies that we have decided that agriculture is the most profitable method of using sunlight. Mr. Pirie pointed out that photosynthesis is extremely inefficient, and the advocates of unicellular photosynthetic organisms, such as chlorella, dispute that farming is the best way to produce food. Algæ have no greater efficiency in trapping sunlight but can be more readily made to work at maximum efficiency by provision of optimum temperature, carbon dioxide, and nutrients. These conditions would render chlorella culture as costly as glass-house cultivation.

Since the green plant will be our main source of food for a long time to come, the best use must be made of it. Only a small part of the crop is eaten directly by man; most is fed to animals or used as a fertiliser, or even wasted. Crops grown primarily as animal food are wasteful, despite the high esteem in which their products are held, because the over-all conversion is usually only 5–10%. Economies in the use of soil can be made both here and by replacing textile fibres by synthetic fibres.

Direct consumption of crops by man is desirable. Plants are, however, relatively poor sources of protein, with the exception of legume seeds and most young leaves. Young, vigorously growing leaves contain up to 30–40% of protein and little fibre, but only a few plant species will stand up to continuous cropping of very young leaves. The alternative is to separate the fibre from the proteins, fats, and carbohydrates of lower-quality leaves.

The advantage of fractionating leafy crops lies in the fact that the products are more valuable when separated than when combined. The proteins are suitable for non-ruminants and perhaps man; the fluid extract could be used for feed or as a medium for micro-organisms; and the fibrous residue still containing some proteins and starches is suitable for ruminants or even for fuel.

In many parts of the world there are abundant leafy wastes, such as potato haulms, sugar-beet leaves, and sweet-potato leaves. When, however, satisfactory techniques have been developed our choice of domesticated plants might well be reconsidered. Plants that use sunlight most efficiently might be chosen rather than those grown merely because a use has been found for them.

On the question of economics, leaf protein, even extracted from crops grown specially for the purpose, would cost less than existing protein foods, and about the same as estimates for yeast and chlorella.

DISCUSSION

Mr. A. L. **Bacharach** pointed out that the successful use of industrial by-products, including leaf-protein filtrate, for the cultivation of micro-organisms depended on a balance between carbohydrate and nitrogen in the medium, and asked whether either would need to be added to these media. Mr. **Pirie** replied that carbohydrates are the limiting factor in many plant juices, and in the case of most waste materials little extra ammonium sulphate is required.

Mr. G. E. **Fogg**, ph.d., agreed that algæ culture is unlikely ever to replace ordinary crops, but suggested that algæ have special features which may make them important as auxiliary sources of food. While their anæsthetic was administered The opening in the fibres, about $^{1}/_{2}$ in in diameter, had a definite firm edge The sac was removed as well as the fat surrounding it, and the hole was repaired with silk

P W HATTINGH

TUBERCULOSIS IN GLASGOW

SIR,—In his letter last week, Dr Horace Joules has committed himself to a statement for which, clearly, he sought no verification Since it is contrary to fact he would not wish it to pass unnoticed

It is not the case that, within the area of South-West Scotland—the territory, that is, of the Western Regional Hospital Board—no consultant in tuberculosis has yet been appointed On the contrary, there are in this specialty fourteen consultants, of whom six are within the City of Glasgow itself At present, three additional appointments of similar grading are in process of being made as a first contribution towards five new appointments, all of which are to be related directly to the re-development of the chest-clinic service in Glasgow which is being carried out as a major capital scheme

Western Regional Hospital Board,
64, West Regent Street,
Glasgow, C 2

A K BOWMAN
Senior administrative medical officer

SIR,—Dr Joules, in your last issue, does well to recall attention to the dangerous breeding-grounds of tuberculosis which explain its continued existence The housing conditions and standard of living today are much better than they were when the late Sir John Robertson launched his attack against tuberculosis in Birmingham over forty years ago We then had four times as many deaths in the slums as in the better housing areas of the city, and having seen the slums and watched their gradual disappearance I can understand why the number of deaths from tuberculosis has fallen steadily from 53,858 in 1916 to less than 14,000 in 1951 This is a public health triumph, as are most of the chief items in the decline in the death-rate

With the terrible conditions such as Dr Joules describes in Glasgow, and such as I have seen in this and many other countries, why do we waste our slender resources on the less profitable specialist propaganda and activity? It is little less than humbug to take, at great expense, infected persons from these breeding-grounds to elaborate chest hospitals (there are few sanatoria in the sense that these treat the general rather than the local condition of the patient) to "profit" by the skill of specialists and nurses and then return them to these breeding grounds for further infection As demonstrated by Sir John Robertson so many years ago, the home could be the best place for the treatment of tuberculosis Home treatment is the least expensive, the most pleasant and stimulating for the patient, and the most expeditious and lasting In the hands of the general practitioner, now provided with more effective medication, success would be achieved But the homes must be improved to permit such treatment The evidence is that good housing and a good standard of living will eradicate the disease and leave the people contented with their desirable happy homes, yet the modern specialist propaganda demands the use of many of our slender resources for an ever-increasing build-up of an elaborate chest-hospital system with its ever-increasing staffs In them there is little indication of achieving or even wishing to achieve the desired eradication, for, as the death-rate diminishes, the propaganda increases and the techniques for treatment are elaborated, and these call for more and more personnel, and the concerted demands of these exhibit a group selfishness[1] which would not be tolerated in any voluntary organisation with limited funds

I am at a loss to see how Dr Joules can reconcile his account of the home conditions with the measures he recommends What value would a consultant in tuberculosis be? Glasgow has medical men quite capable of giving the necessary essential advice Dr Joules's statement that "there has been little or no secondment of nurses from general hospitals to sanatoria or other hospitals where tuberculosis is treated" exhibits one of the selfish demands of the specialist, with such behaviour I am in full agreement with the "doctor prominent on administrative committees" Dr Joules's "intelligent approach to the nursing problem of tuberculosis" would risk the sacrifice unnecessarily of anyone's daughter to tuberculosis True the nurse who is unfortunate enough to become a victim of infection now gets compensation, but I do not regard this as adequate or even justifiable when other better methods should be made possible Such threat of secondment will do more harm to the recruitment of nurses than the "good" its adoption would achieve

His final statement is that "the facts should receive the widest publicity in the national press and on the air, in order that there may be quickening of response to this tremendous human need" He surely has not overlooked the possibility of television! This would permit of the demonstration of magnificent chest hospitals with all their attractive surroundings and their spectacular laboratories with elaborate and expensive equipment Personally I have not appreciated that the specialists are a "tremendous human need" I prefer the general practitioner every time

Birmingham

JAMES F BRAILSFORD

COMPARISON OF PHENYLBUTAZONE AND TAB CODEIN CO

SIR,—The recent statements concerning the efficacy and toxicity of phenylbutazone ('Butazolidin') in the treatment of rheumatoid arthritis led us to devise a small trial to compare its analgesic properties with those of Tab Codein Co *B P C*

Thirty outpatients with established active rheumatoid arthritis were given 2 Tab Codein Co t d s for fortnightly periods During this time they were also given a fixed number of tablets of a distinctive colour, containing codeine phosphate (gr $^{1}/_{8}$) and aspirin (gr 8), and they were told to take as many as they needed of the coloured tablets (up to 8 a day) to obtain relief of pain At the end of the period the number of coloured tablets taken was calculated from the number the patient had left

In the next fortnightly period the patient was given phenylbutazone in a dosage of 200 mg t d s in place of Tab Codein Co, and a similar proviso made regarding use of the codeine aspirin tablets This process was repeated for varying periods up to three months The nature of the tablets was unknown to the patients By this means it was thought possible to assess the efficacy of phenylbutazone as an analgesic, compared with Tab Codein Co, by the number of coloured tablets taken additionally during each period At the end of each trial period the patient was asked if he felt "better," "worse," or "the same", the power of his hand grip was estimated by means of a mercury sphygmomanometer, and evidence of toxicity was sought by interrogation and examination

The results were as follows

	Average no of codeine-aspirin tablets per fortnight	*No of patients claiming*	
		Subjective improvement	*No difference between two drugs*
Phenylbutazone	8	21	6
Tab Codein Co	30	3	

At first sight the hand grips appeared to provide evidence of greater power while patients were on phenyl-maximum efficiency is not greater than that of higher plants, it is easier to achieve higher efficiencies with algæ without elaborate conditions. For example, Prof. E. C. Wassink has obtained efficiencies up to 20% in tank cultures of chlorella in the open: this compares with 2–3% in ordinary crops at their best. The plasticity of metabolism of chlorella allows production of food material of any desired composition—for example, 60% protein and 5% fat, or 10% protein and 80% fat, can be produced by varying the conditions. The ability of certain species to fix free nitrogen of the atmosphere as well as to photosynthesise may have great possibilities.

---

[1] Brailsford J F *Brit med J* 1950 ii 1493

Miss D. F. HOLLINGSWORTH asked whether any research had been done on the use of food yeast. Mr. BUNKER said that this was not very popular as human food in Germany, and was produced there solely as animal fodder. Formerly it was said that only about 15 g. per day could be consumed without causing digestive disorders; this indigestibility was probably due to contamination with defrothing agents. As prepared at present, food yeast is quite palatable.

Mr. F. E. WARNER pointed out various disadvantages in the new foods from the viewpoint of an engineer. If the production of micro-organisms requires the addition of extra nitrogen it might be more economical to feed the nitrogen—say, as synthetic urea—directly to the ruminant. The economy of production of micro-organisms must take account of the vast amount of equipment and power required for aeration and sterilisation, the possible efficiency of sugar recovery from the molasses medium by ion-exchange, and the possible use of fossil fuels for organic synthesis rather than production of natural materials. He questioned Mr. Pirie's statement that straw has a fuel value three times that of the the power required to produce the fertiliser for it, on the grounds of costs and difficulties of transporting straw, its low calorific value, and the lower thermal efficiency of its slow combustion.

Mr. F. WOKES, PH.D., asked whether the biological value of leaf protein had been measured, and whether it would be an adequate protein in the absence of animal protein. Mr. A. E. BENDER, PH.D., pointed out that the published figures for the amino-acid content of gramineæ leaf protein showed only 50% of the requirements of four of the essential amino-acids, and work at Bangor University indicated that the biological value of two fractions of the proteins from cocksfoot grass were 60 and 46. He said that the apparently small quantity—only 2–5%—of yeast recommended for addition to human diets was nevertheless highly effective judging by an animal experiment by Sure (1946). Sure reported that 1% yeast, when added to a diet in which all the protein was supplied by corn, increased body-weight by 50% and biological value by 25%, while 3% yeast increased growth by 250% and biological value by 100%.

Mr. A. L. GREEN, PH.D., likened present attempts to produce new foods to man's early attempts to produce fire, and suggested that present work should be restricted to orthodox methods of food production, which would see us through this century, after which new ideas might present themselves.

Mr. W. E. LE GROS CLARK said that food yeast had been originated as a food primarily for children to increase their protein intake and was used as such in East Africa and the West Indies. He suggested that the taste for food yeast could be developed in a population by feeding it to young children.

The trend of the discussion suggested that present drawbacks to these new foods are largely due to lack of information, and that further investigation is most desirable. Although orthodox agriculture will see us through this century, all methods of increasing the world's food-supply must be pursued, for they are complementary rather than conflicting.

REGIONAL HOSPITAL BOARDS

THE Minister of Health has made the following appoin ments to fill vacancies caused by the retirement of a thir of the members of the 14 boards in England and Wale Out of 124 appointments, 89 are reappointments o retiring members; 6 appointments are still outstandin Those now appointed will hold office until March 31, 195 The names of medical members are shown in bold typ

NEWCASTLE REGION

Reappointed: Edward Crowther, O.B.E.; **S. Whatel Davidson**, F.R.C.P., F.F.R.; Prof. **R. Bramble Green**, F.R.C.S. Arthur Kay; **J. R. Murray**, M.D.; John Lisle, J.P.; Vi countess Ridley; **R. Gordon Russell**, M.B.

New members: James Thomas Fletcher; Miss Barbar Carmichael.

LEEDS REGION

Reappointed: Alderman D. Beevers, O.B.E., LL.D., J.P. H. J. Edwards; B. Hazell, M.B.E., J.P.; W. Louis Lawton O.B.E., J.P.; C. R. Morris, LL.D.; F. Watkinson, J.P.

New member: **R. Watson**, M.B.; one appointment outstanding.

SHEFFIELD REGION

Reappointed: **Hugh Barber**, F.R.C.P.; A. R. Martin; Alderman A. E. McVie, J.P.; T. Pearson, J.P.; Prof. **G. L. Roberts**, M.B., F.D.S. R.C.S.; E. W. Scorer, O.B.E.; Councillor J. S. Worrall.

New members: **R. Lodge**, F.R.C.O.G.; **D. Macmillan**, A. H. Whiteley, M.B.E.

OXFORD REGION

Reappointed: **A. R. Banham**, F.R.C.S.; J. W. W. Cripps; Capt. F. Gardiner, M.B.E., M.C., J.P.; Colonel C. B. Krabbe, O.B.E.; Prof. **T. Pomfret Kilner**, C.B.E., F.R.C.S.; Miss Rosemary Spooner; **J. A. Stallworthy**, F.R.C.S.; one appointment outstanding.

SOUTH-WESTERN REGION

Reappointed: Mrs. Margaret Ball; Mrs. K. A. Goddard, J.P.; Alderman V. J. Ross; Colonel H. Bland Stokes, M.B.E., J.P.

New members: E. C. F. Bird; Prof. J. A. Coutts, M.A., LL.B.; H. M. Scott, J.P.; P. N. Washbourn; **L. W. Hale**, F.R.C.P.; Miss M. H. Cordiner, S.R.N. (until March 31, 1955).

EAST ANGLIAN REGION

Reappointed: **M. W. B. Bulman**, F.R.C.O.G.; J. Grantham, M.A., H. S. Matthes, J.P.; G. T. Vawser.

New members: Sir Stephen Green, J.P.; **Stephen Mackeith**, O.B.E., M.R.C.S.; Captain E. Murray-Harvey, O.B.E., M.C., F.R.G.S.; one appointment outstanding.

NORTH-WEST METROPOLITAN REGION

Reappointed: Prof. **S. J. Cowell**, F.R.C.P.; Alder Lieut.-Colonel G. B. Gond; **A. Staveley Gough**, F.R.C.S.; **D. F. Hutchinson**, O.B.E., M.R.C.S.; H. Lesser, C.B.E., LL.B.; Miss M. Marriott, S.R.N.; J. M. Oakey, M.C., J.P.; Miss **Esther Rickards**, F.R.C.S.

New members: Lord Hacking, B.A.; Prof. A. Bradford Hill, O.B.E., D.SC.

NORTH-EAST METROPOLITAN REGION

Reappointed: **Louis Comyns**, L.R.C.P., J.P.; Lieut.-Commander H. Denton, O.B.E., R.N. retd; Prof. **Victor W. Dix**, F.R.C.S.; Thomas R. Haggarty, L.D.S.; Mrs. Ruth Rees-Thomas, O.B.E.; Major R. P. Woodhouse.

SOUTH-EAST METROPOLITAN REGION

Reappointed: **E. R. Boland**, C.B.E., F.R.C.P.; Lord Cunliffe; R. J. Mellish, M.P.; **A. Talbot Rogers**, M.B.

New members: Miss D. M. Smith, O.B.E., S.R.N.; Mr. H. J. Lester, J.P.; one appointment outstanding.

SOUTH-WEST METROPOLITAN REGION

Reappointed: Mrs. E. Hailstone, J.P.; **Louis Minski**, F.R.C.P.; **M. F. Nicholls**, O.B.E., M.CHIR.; S. R. Thorrowgood; Mrs. H. Feiling.

butazone, but on a "t" test this was not statistically significant

In computing the incidence of side effects, an additional 15 inpatients were included and given the same dosage of phenylbutazone—i e , 600 mg daily Side effects ranging from slight to severe were noted in 34 patients, in 7 of whom it was decided to discontinue the drug These were

Œdema of minimal degree in 6 patients , and gross œdema necessitating withdrawal of the drug in 1 patient
Indigestion (excluding peptic ulceration) in 6 patients (drug withdrawn in 1)
Vomiting (3)
Diarrhœa (4)
Peptic ulceration (2—drug withdrawn)
Ulceration in mouth and throat (3)
Purpuric reactions (3)
Granulocytopenia (2—drug withdrawn)
Dizziness, hyperacusis, and vertigo (1)
Ulceration of vagina (1)
Pyrexia (104°) (1—drug withdrawn)

A complication of phenylbutazone therapy not to our knowledge previously reported is "pink vision," which was observed by patients, not included in the above trial, who were on a dosage of 800–1200 mg daily

These results confirm the general impression that phenylbutazone is a more potent analgesic than Tab Codein Co in the usual dosage given in rheumatoid arthritis

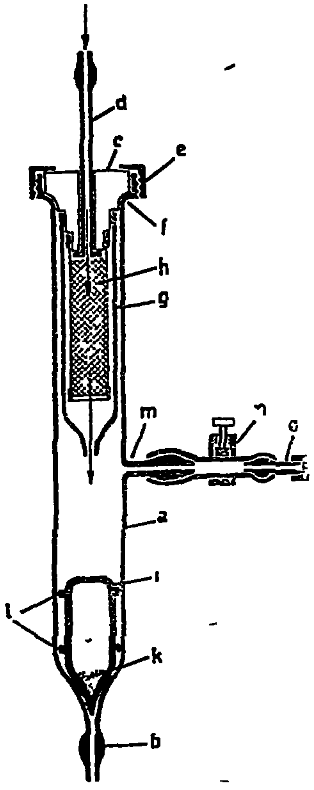
INTRA-ARTERIAL TRANSFUSIONS

Sir,—The articles by Mr Haxton (March 28), Professor Bingham,[1] and others reveal the increasing interest in intra arterial transfusions Therefore I feel that an apparatus that I designed last year to avoid air-embolism in intra arterial transfusion under air pressure might be of interest



This replaces the simple drip chamber and forms a combination of a filter, a drip chamber, and, as an essential part, a floating valve Details are shown in the accompanying figure

The cylindrical glass container (*a*) narrows conically into the tube (*b*) bearing the tubing to the artery Its upper end is closed by the rubber stopper (*c*) with the glass tube (*d*) passing through its centre Hermetic sealing is assured by the metal ring screw (*e*) pressing the upper part of the rubber stopper against the flange (*f*) of the glass container The rubber stopper also bears the cylindrical drip chamber (*g*) and the filter (metal or silk) (*h*) The lower part of the apparatus contains the hollow glass float (*i*), the point of which is ground to fit hermetically into the conical part of the glass container When blood enters the apparatus, passing through glass tube (*d*), filter (*h*), and drip chamber (*g*), the float rises and allows the blood to flow to the artery When, at the end of the transfusion, air under pressure enters the apparatus, the float drops and closes hermetically, thereby preventing air from reaching the artery, and so avoiding the danger of air-embolism The float contains in its interior such a weight of small glass or metal beads (*k*) that its upper part, when floating, just reaches the surface of the blood Several small glass spikes (*l*) on the surface of the float prevent its adhering to the glass container while dropping To the lateral glass tube (*m*) is attached a short rubber tubing with clip (*n*) and a metal conus (*o*) made to fit an ordinary syringe

This arrangement serves four purposes

1 It allows air to escape while blood enters the apparatus
2 It allows injections into the artery
3 It allows the lowering of the blood level if it rises too high (*a*) by injection of air, or (*b*) by letting excess blood escape
4 In conjunction with a sphygmomanometer it allows the measurement of blood pressure in the artery At the same time, of course, the tubing between the blood reservoir and the apparatus must be clamped

All parts of the apparatus are easily and separately detachable for cleaning and sterilisation by boiling or autoclaving

The apparatus will shortly be obtainable from A. Boulliech, 9 rue des Canettes, Paris

Alexandria, Egypt HARRY SCHAEFFER

PATHOGENIC STAPHYLOCOCCI

Sir,—Our experience during the past sixteen months may be of interest From Dec 1, 1951, to the end of March, 1953, 1509 wound swabs, including pus, from various units of this hospital have been received by this laboratory From approximately 42% of these wound swabs pathogenic staphylococci were isolated, and approximately 81% of these staphylococcal infections were penicillin-resistant

Specimens found to contain coagulase-positive staphylococci were as follows

Specimen	*Penicillin resistant*	*Penicillin sensitive*
Wound swabs	519	118
Throat swabs	28	1
Nasal swabs	19	1
Sputa	34	21
Urines	22	6
Cerebrospinal fluid	1	0
Blood cultures	1	2

Bangour Hospital Laboratory
Broxburn, West Lothian
Scotland

ISABELLA A PURDIE

EXCRETION OF MUCOPOLYSACCHARIDES IN URINE

Sir,—We were greatly interested in your annotation[1] on Butt and Hauser's investigations which throw new light on the relation between protective colloids and the physiology and pathology of renal excretion Their results agree with our observations on mice which had been given parenteral injections of foreign protein,[2] and on vitamin-C-depleted guineapigs[3] In the kidneys of these animals the cells of the whole tubular section of the nephron and the tubules themselves contained a considerable amount of polysaccharide, which was not glycogen *These findings raised the question of how such mucopolysaccharides were excreted by the kidney*

After identifying hexosamine containing polysaccharides in normal rabbits' urine, we gave intravenous injections of 80–480 mg of hyaluronate and chondroitin sulphate to rabbits weighing between 1 5 and 2 kg *Part of these substances was excreted in the urine 24 hours after the injection*, the proportion excreted seemed to be inversely proportional to the injected dose, and ranged between 54% and 19% for hyaluronate and approximately between 90% and 31 5% for

Parliament

Hospital Pay-beds

In the House of Commons on April 29, Mr. ARTHUR BLENKINSOP in moving the annulment of the recent regulations on pay-bed accommodation in hospitals,[1] charged the Government with a change of policy in relation to pay-beds. Private pay-beds had always been an anomaly in a health service which had tried to ensure a single standard of service for everyone, and there had always been complaints from those who were told that they must wait for treatment, while those who could afford a pay-bed had been able to get treatment straight away. The regulations, he held, were designed to ensure an increased use of pay-beds, and this would increase the sense of injustice among those who found themselves pushed further back in the queue for free treatment. Furthermore, the regulations undoubtedly added to the favoured position of the part-time as against the full-time specialist. Yet Mr. Blenkinsop thought that it was the position of the part-time specialist which should be re-examined, for there was a great deal of agreement that the full-time specialist gave on the whole the most economical service to the health service. No doubt he would be told that the regulations were designed to ensure that pay-beds were more fully used. But if there were at present unused pay-beds why were they not being used for patients receiving free treatment? Many of these beds, he maintained, were being sterilised for the use of specialists. The regulations were really an excuse for the Minister to avoid finding the extra funds to enable the hospitals to provide an adequate service. They encouraged the extension of a two-level service, one for those who could afford to pay and another at a lower standard for those who could not afford to pay so much.

Mr. FREDERICK MESSER recalled that when the original National Health Service Bill was introduced many felt that the pay-bed proposal was dangerous but that it was justified as an experiment. After five years it had been shown that as a consequence of this provision there were empty beds in hospitals and people waiting for treatment and not able to get into them. The regulations would improve the position of the specialists, who had already not done too badly out of the health service.

Mr. SOMERVILLE HASTINGS pointed out that an increased demand for these pay-beds would increase the cost of the N.H.S. At present almost half were kept vacant. He knew that the Minister wanted these beds used for ordinary patients, but the doctors thought otherwise, and they were on the spot. He had had some experience of these pay-beds and he maintained that there had been a great misuse of them. The doctors pressed to keep the pay-beds empty so that patients could be admitted to them more quickly than to the ordinary beds. Mr. Hastings also attacked the regulations on the grounds of their complexity and vagueness. Their many doubtful and undetermined points were disastrous and would increase the difficulties of those who administered the hospitals.

Mr. ANEURIN BEVAN said that discussions with the Royal Colleges had convinced him that if specialists were not allowed to have private patients in hospitals they would be encouraged to go to nursing-homes. But the colleges believed a specialist could only do his best work in a hospital where the tools of his craft were to be found. Mr. Bevan admitted that he had been reluctant to agree because he saw the provision of pay-beds as a grave breach of the general scheme. The fact that there were empty pay-beds was evidence of maladministration. There was no justification for a hospital to have a waiting-list and empty beds. He affirmed that these beds were kept empty so that specialists could offer a bed at once to patients who could afford to pay. He had always intended that a hospital should be a homogeneity, and that public patients should have access to all the beds of the hospital if there were any beds available. He never intended that pay-bed blocks should be a physical part of the hospital. Some members of the medical profession had proved themselves unworthy of the responsibility with which they had been entrusted. They had used their considerable influence to deny beds to patients, to make them available for their private patients. Furthermore, the extra facilities granted to these part-time specialists were causing a great deal of heart-burning among the full-time specialists upon whom the hospital service mainly depended. Yet these regulations, instead of narrowing the gulf between the status of the part-time specialist and the full-time specialist, widened it.

Mr. IAIN MACLEOD, the Minister of Health, began his reply by saying that with the new regulations he had sent to hospitals a circular stressing that patients should have the system of amenity and pay-beds explained to them. He admitted that the new regulations were complicated but this was because the original regulations in practice had proved inadequate in detail. Their object, he insisted, was not to reduce the charge to private patients, though they might have that result. The object was to carry out fairly the 1946 Act.

Turning to the question of fees, Mr. Macleod said these had been unaltered since 1948, and the profession suggested early in 1949 that alterations should be made. Since then consultations had taken place and the new figures represented fairly general agreement. Boards and committees might, exceptionally, allow an increase from 75 guineas to 125 guineas, for an operation in a field of surgery where complicated new techniques had lately been developed.

The number of section-5 beds at the latest count in February this year, Mr. Macleod said, was 6113, or 1·2% of all staffed beds. The proportion of section 4 beds was 1·3%. It followed, therefore, that 97·5% of all beds in the service were absolutely free, and indeed a high proportion of the beds that were nominally pay-beds were in fact occupied by people under the proviso to section 5. These figures, compared with those for the end of 1950, showed that there had been in 1951 and 1952 a decrease of 4·5% in the section-5 beds and an increase of 13% in the section-4 beds, while the section-3 beds—the free staffed beds—had increased by 18,156, or 4·1%. In view of these figures no-one could conceivably say that the present Government had taken advantage, or would take advantage, of section 5 of the Act to multiply chondroitin sulphate They were excreted largely, if not wholly, in the form of polymerised molecules which liberated hexosamine after acid hydrolysis On the second day no abnormal excretion of polysaccharides could be demonstrated Part of the dose injected was, however, retained, and was possibly metabolised in the tissues Perhaps cells of the histiocytic type are involved, for in organs (particularly the liver) of rats given hyaluronate and chondroitin sulphate intravenously it is possible to see, in the first hours following the injection, a histological picture which can be ascribed to transitory activation of the mesenchyme, with formation of small nodules by lymphohistiocytic cells

GENITAL TUBERCULOSIS

SIR,—Dr Barns and his co-workers (April 25), in discussing reinfection in tuberculous endometritis, have clearly misinterpreted my views I wrote "Pelvic tuberculosis is a blood-borne disease and the focal point must often be outside the gynæcological field"[1] I do not dispute that the endometrium can be infected from the fallopian tubes Sharman[2] has shown that this is not always the method of reinfection Extirpation of the fallopian tubes in four of his patients did not lead to cure of the endometrial lesion

The authors' claim to have shown that genital tuberculosis is an early postprimary manifestation cannot be sustained on the evidence cited "I think there is evidence to suggest that genital tuberculosis, whether latent or active, should be regarded as one of the earliest post primary infections "[3]

CAN CURRENT PRACTICE BE NEGLIGENT ?

SIR,—This grave issue is raised by the case reported by you last week in which £4000 damages was awarded The judge took the view that the anæsthetist had shown "regrettable slackness" in omitting to read Ewing's (1950) paper on Postoperative Paralysis of the Upper Extremity which had been published six months before the operation

Having attended the whole proceedings and heard the judgment, I feel these new dangers must be brought fully home to the profession British law is case law, and this judgment, unless reversed in the Court of Appeal, will carry much weight in future actions of which there are a number already in the list

In respect of the operation and transfusion nothing was done or left undone which in any way departed from widely accepted practice at that time—practice which, in the case of the defendant anæsthetist, had preserved his patients from a brachial palsy throughout his long professional life. Abduction of the arm had been only at an "angle of 80° or thereabouts" combined with the Trendelenburg position The anæsthetist, in conformity with a large section of opinion at that time, regarded 90° as the danger-point Mr Ewing had expressed the view that abduction at any angle was dangerous On the other hand, a consideration of elementary mechanics and my own dissections strongly suggest that added tension from abduction cannot possibly begin until about 45° abduction We still have a lot to learn about cause and prevention in this, as in many things

A judgment that current practice, if it ignores some warning given in a recent journal, can be negligent, is so serious a matter for every one of us that it must be taken to the Court of Appeal and even, if need be, to the House of Lords

Public Health

Fall in Tuberculosis Mortality

FIGURES published by the World Health Organisation[1] demonstrate the remarkable fall in tuberculosis mortality that has taken place in many parts of the world since 1939 Combined statistics from 21 countries (including the United Kingdom), with a total population of 404 million in 1950, show that the death-rate has been roughly halved in the past fifteen years The chief causes are thought to be the energetic mass action directed towards the early detection of the disease by radiography and its prevention by B C G vaccination and the control of milk; improved medical facilities and progress in treatment have also contributed to the success The decline in mortality has been greatest in children and adolescents The male mortality-rate has always been higher than the female and the difference between the two is becoming greater because it is suggested, recent social progress and improvements in hygiene have had more effect on women's living conditions

England and Wales in 1952

The Registrar-General's provisional figures[2,3] for England and Wales in 1952 give a new low record for maternal mortality The figure was 0 59 per 1000 total births, compared with 0 66 per 1000 in 1951, the previous best year The birth-rate of 15 3 per 1000 population was the lowest since 1941, and was 0 2 less than in 1951 The death-rate was 11 3 per 1000 population, compared with 12 5 in 1951, this is the second lowest rate on record The neonatal-death rate was 18 9 per 1000 live births, compared with 18 8 per 1000 in 1951 In 1939 the figure was 28 3 per 1000 The provisional death-rates for all forms of cancer were 2149 per million population for men and 1850 per million for women; the corresponding figures for 1951 were 2120 and 1822 The rise in the male death-rate included an increase from 530 to 567 per million in deaths assigned to cancer of the lung and bronchus; deaths from this cause have now increased by 47% since 1947 The death-rate from respiratory tuberculosis was 212 per million population —a decrease of 23% from 1951 The rate for other forms of tuberculosis was 28 per million, compared with 41 per million in 1951

Estimate of Births

The Registrar-General's final estimate[2] of live births in England and Wales during the quarter ending June 30 is 178,000, and his provisional estimate for the quarter ending Sept 30 is 168 000 The live births registered in the June quarter of 1952 numbered 174,089 and in the September quarter 167,938

the number of pay-beds beyond what was conceived in the original Act.

Dealing with the contention that this was a new policy, which favoured the specialists, Mr. Macleod pointed out that in their comments in the *British Medical Journal* of March 28 the joint committee of consultants had not a word of approval for him. The specialists had in fact wanted to abandon the detailed schedule, but to this he could not agree. They said that they did not want a detailed price ceiling, but a few general ceilings and the specialists would adjust their amounts to the paying capacity of the patients. It was well known how generous the medical profession could be, but Mr. Macleod felt that whatever might happen in the future the time was not ripe for this change. The specialists had also asked for a reduction straight away in the case of pay-beds, but he had pointed out that this was impossible without new legislation, and he saw no prospect of that.

Mr. BLENKINSOP asked what proposals the Minister had in mind to ensure that the empty beds were used for ordinary patients in the hospitals, and Mr. MACLEOD replied he had called for a special report on the question of the occupancy of these beds. As soon as he had the details—and they were almost complete—he would be happy to discuss the matter. The motion was negatived by 261 votes to 233.

Home or Hospital ?

National insurance, Mr. OSBERT PEAKE explained in the House of Commons on April 28, provides for interruption of earning power due to unforeseen misfortunes, or to cessation of earning power in old age, which was inevitable. Motherhood, he admitted, did not readily fall into either category, for most parents did not regard it as a misfortune, it was not inevitable, and it was foreseeable though only for a limited time. But it sometimes meant a loss of earnings and it always brought extra expense to the family. It had therefore been accepted as a proper subject for national insurance. Mr. Peake was moving the second reading of the National Insurance Bill, whose provisions were lately briefly set out in our columns.[1]

Most of the discussion during the debate centred round the new "home confinement grant" of £3 which is offered to a mother who does not have her baby in a free National Health Service bed. There was a growing feeling, Mr. Peake said, that it was unfair that the mother who had saved quite a lot on food and household expenses by having her baby in free hospital accommodation should receive the same amount of benefit as the mother who had her baby at home and had these extra expenses to meet.

Dr. EDITH SUMMERSKILL believed that many harassed hospital authorities devoutly wished that the home confinement grant would induce mothers to stay at home, to leave hospital beds for medical and surgical cases. She was concerned lest the poor woman should be tempted to sacrifice herself for the sake of a few pounds. It was useless to argue that the interests of these women would be safeguarded by midwifery services, because the woman herself had the last word. The doctor, or the health service officials, might say that home conditions were unsatisfactory, and that the woman should go to hospital, but she was free to stay at home. If the extra £3 tended to make a woman sacrifice herself in this way, then the Bill marked the end of an era of enlightened midwifery. No-one would contend that there was no relationship between the record low maternal-mortality rate and the provision of maternity hospitals in the last 20 years. Dr. Summerskill looked forward to the day when every woman would be able to choose between hospital and home in precisely the same way as a wealthy woman could choose between a private ward in a hospital, or even a private nursing-home, and her home. Nor was the obstetrical service offered in hospitals the only consideration. A hospital afforded a mother rest after her confinement which she was often denied in her own home. A hospital confinement, she urged, must not be regarded by the prejudiced as a waste of a bed, but as offering a safe delivery and a period of rest to a woman who had emerged from a trying ordeal and was now to be called upon to tax her resources to feed her baby. Was it surprising, Dr. Summerskill asked, that a third of babies were bottle-fed when we knew the pressure brought upon women to remain outside hospital for their confinement ?

Mr. ARTHUR BLENKINSOP was also anxious lest the new proposals should encourage mothers, who on medical grounds should go to hospital, to have their confinements at home, and he wondered whether provision was being made for the increase in home confinements which he thought we might expect. He did not himself believe that ideally every confinement should take place in hospital. There was a danger that by extending the use of hospital facilities we might get the second best, for owing to pressure on accommodation shorter stays in hospital were being accepted as reasonable. In areas where housing was bad the problem was different and we must watch the effect of the new grant in these areas, where it should be our anxiety to encourage hospital rather than home confinements. He was also anxious that smaller provision was made in the estimates for midwifery services. If we were to encourage confinements at home we must ensure that still higher standards were set for our domiciliary services.

Mr. ENOCH POWELL thought that any measure which tended to take out of the hospital cases which could be dealt with as effectively in the home was a contribution to the efficiency of the health service itself. He suggested that the grant should be large enough to remove a financial obstacle to domiciliary confinement and yet not so large as to weigh the scales unduly in favour of home confinement. He did not think the sum of £3 was excessive.

Mrs. EVELINE HILL pointed out that the women who just could not get into hospital would be grateful for the help of this new grant. Mrs. E. M. BRADDOCK was inclined to believe that the Ministry of Health might use the new grant to urge that there was no need to provide additional maternity-hospital accommodation.

Mr. R. H. TURTON, parliamentary secretary to the Ministry of National Insurance, assured the House that the new grant was fixed at such a rate as to offer the mother compensation for the extra expense of having her baby at home without providing an incentive in determining her choice. The National Insurance Advisory Committee had estimated £2 10*s.* as the extra cost of having a baby at home. According to hospital costing returns the average cost of maintenance in a maternity hospital was £13 16*s.* a week, and the cost of the items the parents would have to pay for if the confinement were at home was £3 5*s.* 8*d.* He was satisfied that £3 was a fair sum. In his view whether the baby was born at home or in hospital was not a matter to be decided by politicians but by the mother on the advice of her doctor.

Food Hygiene

In the House of Commons on April 30, Mr. BARNETT JANNER called attention to the need for further action to encourage cleanliness in the handling of food. In 1951 5797 cases of food-poisoning were notified; in 1952, 6021; and in the first quarter of this year 1035. He understood that doctors agreed that the actual number of cases was much larger.

Dr. CHARLES HILL, parliamentary secretary to the Ministry of Food, said that nowadays this problem was primarily one of germ infection. The old fears of metallic contamination and the like had largely disappeared. It was also largely a problem of meat and milk products—mainly meat. The danger lay in dishes that were not eaten as soon as they were cooked, if indeed they were cooked, but were left exposed to flies. The public should realise that it was not necessarily the food that smelt that was dangerous; the greater danger lay in foods that were not obviously contaminated. It was wrong in the home or in a food establishment for a person suffering from diarrhœa, or from a superficial infection of the skin, however apparently trivial, to handle food.

Smallpox

By noon on May 5 the total of confirmed cases of smallpox in the outbreak in Lancashire and the West Riding was 27, including 7 deaths The 16-year-old Colne Valley boy, mentioned in our report of April 25, died on May 4. He fell ill on April 9 and had been in hospital since April 15 A Leeds mortuary attendant was admitted to hospital on May 2 with what has now been confirmed as smallpox A soldier, who arrived home from Egypt on April 23, was admitted to a hospital near Sheffield on April 27 from his home at Warsop, in Nottinghamshire He may have modified smallpox, but laboratory investigations have so far been negative

Retirement of Dr Clark

Dr W G Clark has recently retired from the office of medical officer of health for the City of Edinburgh Nearly all his professional life has been spent in the public-health service—in Glasgow, where he understudied Sir Alexander Macgregor, and in Edinburgh, to which he was appointed to succeed the late Dr Guy Dr Clark was long a pillar of the Society of Medical Officers of Health, of which last year he served as president He has been an outstanding medical officer of health, with a forthrightness that perhaps owed something to his naval service in the first world war, and his many friends will wish him happiness in his new leisure

Obituary

DAVID THOMAS ROCYN JONES

Kt., C B E, M B Edin., D P H, J P, D L

Sir David Rocyn Jones, medical officer of health for Monmouthshire for nearly forty years, died on April 30 at the age of 80

He was descended from the well-known family of Cardiganshire bonesetters, and his father, David Rocyn Jones, of Rhymney, was the friend of Hugh Owen Thomas From Lewis's School at Pengam, Sir David went to University College at Cardiff, and later he continued his medical studies at University College, London, and at the University of Edinburgh where he graduated M B in 1897 Soon afterwards he accepted the post of surgeon to the Cambrian Collieries in Clydach Vale and settled in general practice in Abertillery He also served as part-time M O H to the town and in 1904 he took the D P H Four years later he became the first whole-time M O H. for Monmouthshire

The rest of his life was thus spent on the Marches of Wales, but there was never any doubt as to which side of the border his sympathies lay He was a member of the court of governors of the University of Wales and of the council of the Welsh National School of Medicine, he was one of the five founders of the Welsh National Memorial Association. He was a Knight of Grace of the Order of St John of Jerusalem in the Priory of Wales, and during the second world war he was chairman of the joint war organisation of the British Red Cross and the Order At one time he was a member of the consultative council of the Ministry of Health for Wales, and later he sat on the Welsh Regional Hospital Board For twenty-five years he was chairman of the Bedwellty division of Monmouthshire magistrates An outstanding personality in Welsh rugby football circles, he was a member of the Welsh rugby union for forty-six years and president from 1947. This long record of public service had earned many public honours He was appointed O B E in 1920, and he was created knight bachelor in 1948 He was also a deputy-lieutenant of his county

Lady Rocyn Jones, who was the daughter of Alderman S N Jones, J P, of Abertillery, died in 1950 One of their four sons was killed in Italy late in the war Of the remaining three two are doctors Mr Nathan Rocyn Jones is orthopædic surgeon to the Welsh Regional Hospital Board, and Dr Gwyn Rocyn Jones has succeeded his father as M O H. for Monmouthshire

LEONARD MORTIMER ROSE

M.A., B M Oxfd, M R C P

Dr Rose, medical registrar to the professorial unit of The Children's Hospital, Birmingham, died on April 28 at the age of 32 He was the elder son of Dr Jack Rose of Baildon formerly of Bradford, and he was educated at Bradford Grammar School

He was a scholar of Queen's College, Oxford, and he graduated B M in 1944 After holding a resident post at the Radcliffe Infirmary he served in the R N V R for three years, partly in H M S *Vanguard* He returned to the Radcliffe in 1947, and the following year he obtained the M R C P After a year as clinical assistant at the Children's Hospital in Sheffield he was appointed R M O at the Children's Hospital, Birmingham, where he later became registrar

Two of his colleagues at Birmingham write "We remember Toby Rose as a somewhat rotund figure, with smiling eyes, he was a cheerful enthusiast, who loved ships and the sea, who had a taste for good cooking and a deep attachment for his pipe and a book by the fireside But doctoring meant more to him than all these things He was a careful observer, a kindly and understanding physician who, although exceptionally gifted, was without affectation, having the simple sincerity of the children among whom he worked Success seemed certain when he had secured an appointment in Vancouver But while he was still working with us illness began to cast a shadow over his usually cheerful disposition He never complained and he never gave in even when the full gravity of his illness became known It is indeed good to have known him "

THOMAS WYPER STEWART

L R C P E

Dr T W Stewart, a senior medical officer of the London Transport Executive, died at his home at Harrow-on-the-Hill on April 20 at the age of 61

He was born at Hamilton, Lanarkshire, and was educated at St Mungo's College, Glasgow, and at Glasgow University While holding a post in the bacteriology section of Glasgow City health department he became interested in medicine, and he began his medical studies while still engaged in this work He qualified in 1920, and after spending a short time as assistant to his brother in Nelson, Lancashire, he was appointed medical officer of health for the Isle of Tiree in the Western Hebrides For seven years he was the only doctor on the isle, a six-hour journey from the mainland by sea—when the sea was not too rough Here he had the valuable experience of handling every medical situation unaided and he came to be greatly respected and revered by the islanders

Anxious as he always was to keep in touch with modern medical developments, Dr Stewart returned to general practice on the mainland at Easdale, Oban In 1929 he settled in practice at Accrington, Lancashire In 1938 he came south to Whiteparish, Salisbury, before starting a new practice in Perivale, Middlesex Owing to war-time difficulties and the serious illness of his wife, he gave up practice and accepted an appointment with the Ministry of Pensions, becoming deputy commissioner of medical services in Leeds Ten years ago he joined the staff of London Transport

L G N writes "In all his medical career, although his roving instinct seldom let him settle for long, Dr Stewart took an exceptional interest in the welfare of his patients He was blessed with a lively sense of humour, which made him a most entertaining companion His stories of his experiences on Tiree were told with a racy Scottish wit, and he delighted to relate, for instance, how in his limited Gaelic he once informed a patient that she had given birth to a fine cockerel, the lad, needless to say, was known thereafter by this pseudonym

"He was more sensitive than appeared on the surface and he was essentially a shy man He was a loyal and generous friend In his later years he set an example to younger colleagues of the highest standards of personal and professional qualities, and he always made his points with a deftness which earned him their admiration and respect Dreading retirement, he vowed that he would die 'in harness'; and happily his wishes were met, It was essential for people to wash their hands before handling food and also after using a lavatory. Unsatisfactory conditions, he pointed out, were preventable, and admirable work in health education was being done by the Central Council for Health Education, the St. John Ambulance Association. the Red Cross. and some firms and trade associations. On the initiative of Dr. Belam, the M.O.H. for Guildford, food guilds had been formed in various parts of the country to make clean-food principles better known among the general public. Today eating in the mass was much more common than it used to be, and one careless food-handler could infect 200 or 300 people. We could not deal with this problem on the basis of the Factory Acts as an offence. It was, Dr. Hill held, a matter for health administration, and for persuasion rather than regulation. The solution must lie in the field of personal conduct, but he admitted that present legislation could be improved.

QUESTION TIME

National Health Service Expenses

Mr. JOHN MORRISON asked the Minister of Health the total cost of meeting loss of remunerative time and for travelling and subsistence expenses sustained by members of all boards and committees established under the National Health Service Act for the year ended March 31, 1952.—Mr. IAIN MACLEOD replied: About £105,000.

Mass Radiography

In answer to a question, Mr. MACLEOD stated that since the inception of the mass-radiography units 10,644,695 cases had been X-rayed up to Dec. 31, 1952.

Dentists' Fees

Mr. HENRY PRICE asked the Minister whether he was able to make a statement on increased National Health Service fees for dentists.—Mr. MACLEOD replied: The Secretary of State for Scotland and I have informed the British Dental Association that we are ready to embark at once on an inquiry to obtain all the facts about dental remuneration, but that the information at present available is not in our view sufficient to justify any immediate increase.

Mr. PRICE: Does this mean that the dentists' demand for the restoration of the 10% cut has been rejected? Does he realise the disappointment and anxiety that this will cause among what might be called the depressed section of this profession which is almost entirely dependent on the National Health Service?—Mr. MACLEOD: Yes. It means that the claim for the restoration of the 10% cut has been rejected, because I do not think I have sufficient evidence. I have a duty to the dental profession. but equally I have a duty to the taxpayer, and I must discharge both.

Ministry of Health Statistical Unit

Mr. A. BLENKINSOP asked the Minister whether he would set up a statistical unit in his department to assist both in publishing more information for the general public and in providing detailed figures for the use of the department.—Mr. MACLEOD replied: This method of collecting statistical material has not so far been adopted, but I always have this subject in mind and I shall have to consider, as experience grows, whether it is necessary to alter the present arrangements for the purposes mentioned. There is a flood of information coming in now about costing and other financial aspects of the health service. If I can set up a department without exceeding my present establishment, I think it will be more convenient to keep it centrally within my Ministry.

Prices of Proprietary Products

Mr. BLENKINSOP asked the Minister whether he was in a position to make a statement arising out of his discussions with manufacturers of pharmaceutical goods about the prices of proprietary brands.—Mr. MACLEOD replied: Not at present. Mr. BLENKINSOP: Can the Minister say when he hopes to be able to take some action on this matter, which, after all, was referred to by the Public Accounts Committee some considerable time ago?—Mr. MACLEOD: I have taken a good deal of action on the lines recommended by the Public Accounts Committee, and this is a matter which, without going into details, I can say is under very serious consideration by the Government.

In England Now

A Running Commentary by Peripatetic Correspondents

SURGEONS are strangely quiet in their official attire. Once introduced to the blaze of academicals in other branches of the profession, a Martian or other foreign visitor might well undervalue these douce blackbirds with nothing more ornamental about them than a couple of red stripes down the front. But when they received Her Majesty the Queen, their most distinguished Honorary Fellow, in Lincoln's Inn Fields last Tuesday, the vast blue and white marquee supplied plenty of colour—from the massed flowers, and fine needlework chairs on the dais to the modest but telling creations worn by the ladies. The memorial stone, with its simple inscription, dangled above its pillar, the band played popular airs, the arc lights shone, and the boards of the faculties processed to their places at exactly the moments appointed. And so with royal punctuality did Her Majesty. All went perfectly: the casket filled with historic documents was closed and laid in its place, the stone, after a momentary hesitation, sank majestically down on it, and the Queen declared it well and truly laid. All who were there will remember that engaging look of interest and pleasure by which our national life is now so often refreshed.

* * *

The versatility of the human mask is only equalled by the variety of techniques for transferring it to canvas. This year's Royal Academy exhibition fairly beams with portraits, and by far the greater part of them, in spite of being orthodox, are good. It is perplexing to know why a good, careful likeness by a competent artist should be so much better than a photograph. A colleague tells me it is because the camera can only crystallise a moment of time, while a painter can bring to his picture a whole background of knowledge—not only of his sitter's character and qualities, but of the nature of physical movement—the notion of carry-through to the completed act. I think this theory applies well to the portrait of *Ralph Vaughan Williams, O.M.*, by Sir Gerald Kelly. A camera might equally have caught him turning in a chair: it could hardly have conveyed this sense of a man of many friends, all of whom know this familiar movement, presently to be completed: that has been given us by the painter's apperception of many kinds of data. Harold Knight's beautifully painted likeness of *The Rt. Hon. Sir Travers Humphreys* has this same kind of insight, and so has Dr. Henry Lamb's portrait of *Prof. T. R. Elliott*. Once I was fairly launched on the portraits I sought familiar faces; but, apart from Professor Elliott and the benign bronze head (by David McFall) of *Hugh J. Taggart Esq., F.R.C.S.* doctors, were strangely rare this time. There was, of course, Sir Alexander Fleming (by Henry Carr), looking well in red velvet sleeves; and there were a fair sprinkling of D.SC.S, Mrs. Marie Stopes among them—the pale yellow taffeta and scarlet cloth of her gown so exquisite (thanks to Sir Gerald Kelly again) that no other academic dress could compare with it. Many faces might have belonged to doctors, and I hurried in turn from Sir Thomas Beecham (misleadingly wearing a white gown, and looking, even under the inspired hand of Simon Elwes, every inch a senior surgeon) to Arnold Mason's *Gilbert P. Norton, Esq., C.B.E., D.S.O., T.D., D.L., F.C.A.* (who could surely have squeezed in an M.B. somewhere among that lot) and Alfred R. Thomson's *Grahame B. Tubbs, Esq., F.R.I.B.A.*, who seemed built for the part of family physician. One face which I had confidently decided could *not* belong to a doctor, bore the disconcerting title, *Portrait of a Gentleman*. The only other pictures of medical interest were a pleasant landskip, *At Birdham, Sussex*, by Adrian Hill, the pioneer of art therapy in hospitals. John Wheatley's very good painting of the chairman of the Sheffield Regional Hospital Board, and a jaunty little view by John Cole of a chemist's shop in Wigmore Street.

I spent so much time looking for a doctor that I saw very little of the other pictures. Here and there, however, my eye rebelled, and lingered on something pleasant: on the subtle pink of the sky in Edward Bawden's *Hadrian's Villa*, on Stanley Spencer's mongoloid but entirely delightful pale-coloured children climbing through for he was actually working until the day of his death He leaves behind a memory of devoted service which his friends and colleagues will never forget "

Dr Stewart married in 1912 Janet Miller Dyer, of Hamilton, Lanarkshire She survives him with a daughter and a son who is also a doctor

Notes and News

N.H S ACCOUNTS

EXPENDITURE on the National Health Service in England and Wales during the year ended March 31, 1952, is set out in the Summarised Accounts now published [1] with the report of the Comptroller and Auditor General thereon The corresponding report for Scotland has already appeared [2]

Among the subjects discussed by the Auditor General are the joint purchase of supplies by hospitals in the same area , the financial deficit on hospital farms and gardens, which amounted to £614,033 , and the inadequacy of store accounts and inventories at many hospitals

A foreword to the Accounts shows the average weekly cost of maintaining a bed in 717 ' wholly general " hospitals in 1951–52 as £18 5*s* , which may be reduced to £14 5*s* 11*d* by adjustment to exclude notional outpatient expenditure, and to £12 5*s* 9*d* by further adjustment for vacant beds A table shows how this £18 5*s* is composed The running charges of £4 13*s* include £1 17*s* 10*d* for provisions and £2 0*s* 2*d* for drugs, dressings, &c The total standing charges of £14 11*s* 6*d* include £2 15*s* 4*d* for doctors' salaries, £4 3*s* 1*d* for nurses' salaries, £5 7*s* 7*d* for the salaries and wages of other staff, and 19*s* 5*d* for fuel light power, and water, but they are reduced to £13 5*s* 11*d* by certain direct credits, including receipts from staff for board and lodging

The Auditor-General recalls that since March, 1950, the Ministry of Health has had a central investigation unit charged with reporting instances of extravagant prescribing and says that in the thirteen months ended Dec 31, 1952, reports were made on 282 doctors who appeared to have been prescribing excessively Most of these were visited by the Ministry's regional medical officers, and in addition warning letters were sent to over half of them As a rule (the Ministry stated) the doctor's coöperation was obtained and substantial economy in the cost of prescribing was secured without detriment to the treatment of patients , but reports on 11 doctors who apparently continued to prescribe excessively were referred to the local medical committees Fines of £50 and £250 were imposed on one doctor, the cost of whose prescriptions in one month was £972 compared with an average of £172 for patients' lists of similar size in the same area , and smaller fines were imposed on two other doctors

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

IN the school's department of public health, under the direction of Prof J M. Mackintosh, students continue to work in groups on chosen subjects Evidently they value this experience , for, according to the school's report for 1951–52,[3] an overwhelming majority have declared that they find it more interesting than classroom work, and 55% have thought it more effective Among the surveys by different groups was one of family welfare, which revealed, among other things, the importance of the pilot survey, the lack of universally accepted technical terms for sociological studies and the need for careful classification of headings to avoid differences of interpretation and for the use of accepted statistical methods of handling data. Another group investigated the maternity services of a London administrative division, and discovered important deficiencies—lack of integration, discontinuity of supervision, and little attention to the educational aspects of antenatal care A third group set out to discover, by means of a questionary, the effect of hardness of water on the domestic consumer In a hard-water district in London housewives were spending more on soap then housewives in a soft water district in Birmingham The group found that to soften all of London's water would be impracticable , but in smaller units—for example, blocks of flats—the cost of a softening plant would probably be met by the saving in soap One of the other groups studied adoption and came to the conclusion that there should be research into the efficiency of the present system of placing children , at present, after the adoption order has been made all official contact with the child ceases

[3] Report on the Work of the School for the Year 1951–52 London School of Hygiene and Tropical Medicine (University of London) incorporating the Ross Institute Keppel Street Gower Street London W C 1

The Barbed Wire Fence, on the stout reliable characters in Alfred Daniels's *Village Wedding*, on the delicate minute brilliance of S. R. Badmin's *A Bright Winter Day*, on Erich Wolfsfeld's yawning studies of a baby, and on the superb wintry weather of Leslie C. Worth's *The Market Cart*, which I should like to own. Sir Winston Churchill, in his un-Gartered days last year, painted a bold and cheerful view of *Cap d'Ail*, and Sir Alfred Munnings has painted, several times, that friend of man, and of Sir Alfred Munnings, the horse. Among the sculptors, Willi Soukop has achieved the impossible by combining Rossetti with Henry Moore in his *Woman Waiting*.

* * *

I used to wonder why my late chief, an excellent diagnostician, would occasionally send a patient into hospital with a diagnosis wide of the mark. But now I understand. The difficulties of consulting in the home, compared with the serene and objective atmosphere of a hospital, are striking. There is the air of apprehension, most obvious if one makes the mistake of allowing relatives to remain in the room during the examination. Then there are physical hazards—poor lighting, bizarre garments that cling like limpets and defy efforts at removal. In poor homes, a mixture of filth, sweat, and pallor often gives a frightening but false impression of moribundity which disappears magically in the ward. Worst of all, it is often necessary to examine the patient from the " wrong " or unaccustomed side. Why, in the name of Heaven, are teachers and examiners so obsessed that students should always learn to approach the patient from one side only ? Outside a hospital, this is quite impracticable, unless one is accompanied by a carpenter. For the bed is often fixed against a wall and an ill patient cannot always be moved around to the other end, apart from the absurdity of doing so. Students should surely be taught to be equally familiar with the examination of a patient from either side of the bed.

* * *

Most doctors spend a great deal of time in work outside their usual routine for which they get no credit. Getting credit is perhaps putting it badly. There is no credit in doing what you like of your own free will. For several years my own particular sideline has been psychotherapy —of the superficial kind, I hasten to add. (I never refer to those two well-known characters Uncle Œdipus and Auntie Electra.)

Out of curiosity I counted up the time I had spent on N.H.S. patients during the past quarter. The interviews took place by appointment usually on Saturday and Sunday, and in the evenings after surgery hours. Each lasted an hour. It was a light quarter, for the influenza curtailed my free time. Even so the total came to 102 hours. Of this time three patients shared 72 hours between them. If I added 12 hours for instruction courses and another 12 at least for writing up case-reports, the total came to 126, and yet I could have usefully put in three times as long. The present epidemic-free quarter will, I hope, be more leisured, and I expect to top the 200.

I know plenty of colleagues who do the same. We do not complain, and we are not even asking for more pay, for the very simple reason that we like doing it. But isn't it a good thing for our patients that we do ?

* * *

Thanks largely to the duty on the stuff that cheers and inebriates we are a tight little island no longer. On the other hand, more of us smoke and many of us who smoke smoke more than we used to and more than we can afford. It is also true that more and more of us lead what Dr. Ffrangcon Roberts describes as " a medicated existence." Is there not perhaps some connection between these facts ? It looks as though most people must have something to help them to cope with modern conditions of living : beer or barbitone, sherry or sedatives, vodka or valerian. If the price of honest liquor were drastically reduced might there not be a more than corresponding reduction in the national drug bill ?

Letters to the Editor

THE PROBLEM OF PEPTIC ULCERATION

SIR,—Sir Heneage Ogilvie writes so well and so convincingly that one almost begins to feel one's surgical beliefs slipping. I see, however, from his letter (April 11) that he is not averse to criticism, and so I venture to question some of the conclusions in his lecture published in your issue of March 21.

In the first place, there seems to be some confusion about the Finsterer partial gastrectomy. In company with some colleagues I paid a visit to Professor Finsterer's Clinic in Vienna, between the wars ; and the operation which we saw him regularly perform, and at which we assisted on several occasions, was not one of his own devising but the Hofmeister partial gastrectomy. This Finsterer acknowledged.[1]

In this operation the upper half of the cut surface of the stomach is closed and embedded, and the jejunum is anastomosed to the lower half behind the transverse colon. The proximal loop of the jejunum is sutured to the stomach for a little way to cover the junction of the embedded and anastomosed portion, and the transverse mesocolon is sutured to the stomach proximal to the anastomosis. Even with this lower attachment the transverse mesocolon is dragged upwards and away from its natural position when the clamps are released, and the stomach remnant rides high beneath the dome of the diaphragm.

It must be granted that in this operation there is little regurgitation or vomiting of bile, and the stomach empties rapidly—too rapidly, in fact—giving rise to the dumping syndrome.

Partial gastrectomy does not necessarily ensure that the patient will not develop an ulcer of the anastomosis or in the jejunum. If this happens the surgeon must undertake an operation which in the first place he sought to avoid, and which in the second place is made infinitely more difficult by the anastomosis being retrocolic. If the operation has been done anteriorly the structures are, so to speak, to hand without a difficult dissection. For these reasons I some years ago abandoned the retrocolic anastomosis.

As Sir Heneage says, every surgeon has his own pet way of doing partial gastrectomy, and I apologise for boring the reader with one which I have found most satisfactory.

The great omentum is removed with the amount of stomach adequate for the particular case. The cut surface of the stomach is closed for a short distance at the lesser and greater curvature, thus leaving a central opening to which the jejunum is anastomosed in front of the transverse colon giving a stoma of about two to two and a half inche [illegible] jejunum is applied by seromuscular suture to the s[illegible] above and below, as well as around, the stoma. Thus is formed an upper and lower valve in the stomach to ensure slow emptying. The operation is completed by the anastomosis of the proximal to the distal loop of the jejunum. This adds about another ten minutes to the operation, but it is worth while for it prevents immediate and remote regurgitation or vomiting of bile. With this operation there is no ' dumping,' and it does not seem that the transverse colon lies heavy upon the loops of the jejunum, nor have I experienced difficulty in bringing the loop of the jejunum to the lesser curve in front of the colon. If such a difficulty did occur I see no reason why the mesentery should not be lengthened after the practice of Yudin. The bowel here is very well supplied with blood-vessels, and division of a few evidently runs no danger of damage to gut.

Sir Heneage has a poor opinion of gastrojejunostomy as surgical treatment for duodenal ulcer. Some time ago Sir Robert Hutchison invited him to have a look at the statistics of James Sherren[2] and Sir James Walton[3]

HALLUX VALGUS

In a recent letter[1] Mr Charles A Pratt, M C S P, mentioned the difficulty of buying shoes—correctly designed with a straight inner border—which would not favour the development of hallux valgus Messrs Hardy & Son, of 6, Baker Street, London, W 1, inform us that they have been making shoes for customers with difficult feet since 1903, and are now in the act of developing a wide range of shoes with straight inner borders Unfortunately they have given these the name of "corrective footwear," where "normal footwear" would have been more appropriate But it is useful to know that shoes of this kind are, in fact, on the market for all to buy

COURSE FOR MATRONS

King Edward's Hospital Fund is arranging to hold in London residential management training courses for prospective matrons and assistant matrons The first course will consist of three terms of about six weeks and will begin on Sept 28 Hospital management committees and boards of governors in the four Metropolitan regions are asked to nominate candidates from among their sisters by May 28 The course is free and employing authorities will be able to grant study leave with pay Further particulars may be had from the director, Division of Nursing, King Edward's Hospital Fund for London, 21, Cavendish Square, W 1

FOOD-SUPPLIES, POPULATION, AND WAR

On May 2 the Medical Association for the Prevention of War held a conference in London at which Dr Duncan Leys recalled questions raised by Prof A V Hill in his presidential address last year to the British Association Professor Hill had suggested that scientists in the "free countries" faced a moral dilemma in the question Are we justified in doing good when the foreseeable consequence is evil? "Doing good" in this context meant the application of modern methods for the prevention and cure of disease in areas where it was thought that the population threatened to outrun the food supply But, said Dr Leys, the destiny of the peoples of Asia lay in their hands, not in ours It would be presumptuous for the peoples and scientists of Europe and the U S A to suppose that they had it in their power to influence—except perhaps in minor ways and very temporarily—the course of events in Asia As to birth control Dr Leys thought it a savage irony that this could be held up as a sort of threat to the people of Asia—"Limit your families or else " What was needed was the *right* of easy access to methods of birth control, and this was denied even to women in Britain at the instance of people with the highest moral principles This right would no doubt be established all over the world, but Dr Leys believed that the building up of higher standards of life would be the most important factor in reducing birth rates With the immense new possibility of manipulating the environment, it was morally wrong to have peoples in different parts of the world with greatly differing standards of life the world was one

Prof J B S Haldane, F R S, dealt with the malthusian view held, it seemed, by Professor Hill—that the growth of a population is restricted by food-supplies, that famine sets a limit to the increase of a species In Professor Haldane's opinion this view could not be sustained Populations had fluctuated among birds and mammals which had been long and carefully observed, but no disastrous fall of a population due to competition for food supplies ever occurred In general the same was true of the human species Industrialisation in a country was constantly observed to affect the growth of its population After a generation or two the birth rate tended to fall, and this would probably happen in India and other Asian countries as had happened in the West

Mr N W Pirie, F R S, said that over population of the world was not imminent since the possibilities of increasing the production of food on a world scale were enormous even with present agricultural methods supplies could probably be trebled or quadrupled Nevertheless there was a need to develop more satisfactory methods of birth control so that the birth rate would reflect a demand for children and nothing else

Prof L S Penrose, F.R S, questioned the assumption made by several speakers that over population led to famine, which in turn led to war The Nazi demand for *Lebensraum* had been useful as propaganda for an expansionist policy but was not supported by facts In fact, there was no evidence that any European wars had been due to such a sequence of events

THE EYE OF THE BEHOLDER

Prof János Plesch, who has made a long study of Rembrandt, approaches his subject somewhat individualistically in a new book[1] He has given much thought to the special character and setting of the master's work, and moreover of their impact upon the beholder In particular, he has investigated the "subsidiary" and "spatial" *figures*, which he claims exist in a considerable number of the paintings, etchings, and drawings In illustration of this thesis, the volume contains a series of plates, the figures in question being indicated by arrows Dr Plesch implies the subjective nature of much of his material by suggesting that success or failure to perceive these figures is a test of artistic sensibility On somewhat firmer ground is some evidence for Rembrandt's high degree of hypermetropia, and its effect upon his rendering of contours Finally, the position of Rembrandt in relation to the historical significance of syphilis is discussed in an appendix

University of Oxford

At a convocation to be held on July 1 in celebration of the centenary of Cecil Rhodes and jubilee of the Rhodes scholarships, the honorary degree of D C L will be conferred on a number of former Rhodes scholars, including Prof W G Penfield, O M, F R S

Royal College of Physicians of London

for this operation—very indigestible stuff, it must be granted, for a confirmed gastrectomist. I had the good fortune to work for these two surgeons, and so was in a position to appreciate not only their skill but their results, which are sometimes different from statistics. Their results were outstanding, for, as Sir Robert Hutchison [4] and Dr. Christopher Howard [5] have emphasised, they knew how to do the operation, and, what was more, they knew when not to do it. Their experience taught them that there were cases not at all suitable for the operation, not only on pathological but also on anatomical grounds. Here is an example—the last case on which Sherren operated before resigning from the London Hospital:

> At operation the patient, a man in the early fifties, was found to have a large mass at the pylorus. Sherren, with all his experience, could not decide on the nature of the tumour. Removal was out of the question, and he decided to do a short-circuit. The transverse mesocolon was fat-laden, and the lesser sac practically obliterated by adhesions. He brought the jejunum through the omentum in front of the colon and anastomosed it to the greater curvature of the stomach, from which the gastrocolic omentum was cleared for the required distance. The patient did well until the 16th day, when he died suddenly from coronary disease. Necropsy showed that the tumour was caused by inflammatory reaction due to duodenal ulcer on the posterior surface. The ulcer had practically healed except for a tiny portion in the centre. Sherren did not use a clamp on the jejunum for fear of causing a clamp ulcer, nor in his anastomosis did he remove any mucous membrane from the stomach or jejunum. It was almost impossible to identify the line of anastomosis, but there was a well-marked clamp ulcer of the stomach which was also in the process of healing.

Sherren and Sir James Walton believed that if it were possible to cure a patient's duodenal ulcer, and still leave him with the whole stomach, this should be done: better a whole stomach than an austerity remnant with its dumping syndrome and all that. It was not that they shied away from the operation of gastrectomy, for I have yet to see a surgeon who could surpass them in the art of gastrectomy. Nor was it that they failed to recognise the complication of anastomostic or jejunal ulcer; for they were among the first to recognise it, and none was more competent to deal with this complication. Their mortality for gastrojejunostomy, plus that of gastrectomy for the complication of anastomostic ulcer, was infinitely less than that of those who did gastrectomy only for duodenal ulcer.

It is remarkable that at the time when Sherren and Walton were getting such good results with gastrojejunostomy, the Mayo Clinic claimed 94% success for the operation, and Moynihan said of the operation: "I am an ardent and sanguine advocate of this operation than which I think there is none in all surgery more completely satisfactory."

Perhaps stomachs have altered much in the last quarter of a century. The British stomach may have lost its phlegm and turned sour under the weight of taxation and restrictions, but I think some discretion ought to be exercised in selecting cases for gastrectomy, particularly with regard to age. Unless there is real need stomachs should not be sacrificed, and lives hazarded, on the altar of gastrectomy. Doctors themselves when afflicted with duodenal ulcer do not rush to operation, and they have gastrectomy done on themselves only when this is a dire necessity. Charles Mayo, who was no fool in surgery, was reputed to have said: "A man who would take away a large part of my stomach for a small ulcer in my duodenum would have to run faster than I!"

London, W.1. MICHAEL SMYTH.

NOTIFICATION OF TUBERCULOSIS

SIR,—I quote from the latest instructions on the notification of tuberculosis issued by the Ministry of Health:

> "A person who should be notified as 'suffering from tuberculosis,' therefore, is a person who, because of tuberculous infection, may infect others: or a person who is suffering from an active tuberculous lesion which calls for medical treatment or for some modification of the patient's normal course of living."

A child suffering from the (usually mild) disease caused by primary tuberculous infection does not fall into either of these classes, and so is not to be notified. Yet a search among the contacts of such a patient may be most fruitful in revealing hitherto unknown sufferers from phthisis. Why does the Ministry deliberately discard this most valuable weapon?

Whipps Cross Hospital, London, E.11. E. HINDEN.

PROFESSIONALISM IN THE HEALTH SERVICE

SIR,—May I comment on the letters you have received on this subject.

I have been accused of uttering "severe strictures" on the medical profession but no-one has said which of the alleged strictures is untrue or stated unfairly.

Dr. Lindsey Batten (May 2) has, I think, overlooked the fact that besides industries productive of material goods there are industries that exist to produce services. But however the N.H.S. is regarded, the efficiency of its organisation and operation is important if what is done to give "medical aid, comfort, and advice to those citizens who need or ask for it" is not to fall short of what could be done with the knowledge, people, and resources available. That is how I view efficiency, and I believe that for its attainment we are largely dependent upon the actions of the free self-governing professions.

Against Dr. Walshe's pronouncement on the distinctive features of a profession (April 25) may be set the conclusions of several authorities (e.g., T. H. Marshall, and Lewis and Maude) who have published dispassionate studies on the subject.

London, N.W.11. L. FARRER-BROWN.

TREATMENT OF ADVANCED MALIGNANT DISEASE WITH RADIOTHERAPY AND A.C.T.H.

SIR,—The letter from Dr. Houghton and Dr. Walter (April 18) calls attention to the possible applications of adrenal cortical hormones in conjunction with radiotherapy.

A case of advanced malignant disease, treated by us with X-radiation and cortisone, has given results similar to those reported in their series.

> The patient, a man of 65, had a primary squamous-cell carcinoma of the pyriform fossa with secondary deposits in both groups of cervical nodes. These formed large masses, measuring 13·5 × 8·8 cm. on the right side, and 8·8 × 7·8 cm. on the left. The larger group of glands had ulcerated a small area of the overlying skin. A course of radiotherapy with 220 kv. X rays was given to both sides of the neck on two fields of 15 × 15 cm.; a total dose of 4020r was given to each field in 28 days, with a maximum skin dose of 4500r.
>
> On the 10th day of treatment cortisone acetate (Merck) was administered in a dose of 120 mg. This dose was repeated each day for 21 days, and was then gradually reduced to zero in a further 8 days. Symptoms of radiation sickness (general fatigue and anorexia), which had appeared before cortisone therapy was commenced, disappeared within 24 hours and did not recur throughout treatment. Erythema of the skin of the neck appeared on the 20th day of treatment; the skin reaction was slight and did not progress beyond the stage of dry peeling. A moderate membranous reaction was produced on the pharynx, but the patient was free of dysphagia throughout treatment. On the 20th day of treatment the patient developed signs of bronchopneumonia at the base of the left lung, associated with a raised temperature and

Institute of Dermatology

No charge is being made for attendance at the lectures of the summer course, to be held at the institute, Lisle Street, London, W C 2, during May and June

Nuffield Provincial Hospitals Trust

The Investigation into the Functions and Design of Hospitals has moved from 33, Doughty Street London, W C 1, to the Trust's headquarters at Nuffield Lodge, Regent's Park, N W.1 (PRI 8871)

Empire Rheumatism Council

Lord Horder has resigned from the chairmanship of the council Dr W S C Copeman, who has been medical secretary of the council for nearly 18 years, succeeds him

Newsholme Lectures

Prof Alan Moncrieff will deliver the Newsholme lectures at the London School of Hygiene and Tropical Medicine, Keppel Street, W C 1 on Tuesday Wednesday, and Thursday, May 19, 20 and 21, at 5 15 P M He will speak on Child Health and the State

St. Bartholomew's Hospital, London

The hospital is holding an exhibition of its historical documents and other treasures on Thursday, Friday, and Saturday, May 14, 15, and 16 The exhibition will be open to the public each day from 10 30 A M to 6 30 P M (Note change of times of admission)

Ross Institute Industrial Advisory Committee

At a meeting to be held by the committee at the Rubber Growers' Association, 19, Fenchurch Street, London, E C 3, at 2 15 P M, on Thursday, May 21, Mr C R Harrison, chairman of the committee, will open a discussion on Tropical Health Problems and their Connection with Industrial Relations, and Prof George Macdonald, director of the Ross Institute, will speak on International Health Work

Society for Endocrinology

The following office bearers have been elected chairman, S J Folley, hon secretaries, C H Gray and N F Maclagan, hon treasurer, G W Harris, editor of society's proceedings, S Zuckerman, members of committee, T Mann, C J O R Morris, I W Rowlands, and S L Simpson Communications should be sent to the hon secretary, Department of Chemical Pathology, King's College Hospital, Denmark Hill, London, S.E 5

Laboratory Animals

The Laboratory Animals Bureau is holding a symposium at 1 Wimpole Street, London,-W 1, on Thursday, May 14, at 2 30 p.m Dr H J Parish will be in the chair Mr A N Worden, M.R C V S, will speak on the Feeding and Husbandry of Laboratory Animals, Mr A. E Mundy on the Function of the Animal Technician, Mr J Scarnell, M R.C V S, on the Control of Infection in Small Animal Breeding Units, and Mr J S Paterson, PH.D M R C V S, on the Provision of Animals for Research Further particulars may be had from the bureau, M R C Laboratories, Holly Hill, London, N W 3

British Occupational Hygiene Society

A meeting to inaugurate this society was held at the London School of Hygiene and Tropical Medicine on April 27 The founder members include—as well as doctors—engineers, chemists, and physicists, who are concerned with the maintenance of healthful conditions of work Mr T Bedford, D SC, director of the Medical Research Council's environmental hygiene research unit has been elected president, Mr E J King, D SC, professor of chemical pathology in the University of London, president elect, Mr P C G Isaac, lecturer in public health engineering, King's College, Newcastle upon Tyne, hon secretary, and Mr D E Hickish, of the department of applied physiology, London School of Hygiene and Tropical Medicine, hon treasurer

The Lister Institute of Preventive Medicine

Prof W T J Morgan, F R S, has been appointed deputy director of the institute

The institute has recently accepted a charitable endowment from Messrs Arthur Guinness & Sons, for the establishment of a Guinness Lister research unit in general microbiology Dr B A. D Stocker has been appointed as head of the unit, and he will take over his duties in October

Dr Stocker is 35 years old After a war career in the medical branch of the R.A.F V R, with which he served mostly in India and Burma he was successively demonstrator lecturer, and senior lecturer in the department of bacteriology and immunology at the London School of Hygiene and Tropical Medicine His research work has been directed mainly to bacterial genetics, particularly mutation rates of flagellar antigens in *Salmonella typhimurium*; and during the ten [illegible] United States, with [illegible] Fund fellowship in the [illegible] the transduction of [illegible] pneumococcus and with [illegible] bacteriophages in which he applied the discoveries of Zinder and Lederberg to the transduction of flagellar characters in salmonella leucocyte-count. This infection responded to penicillin, without cessation of cortisone therapy. 10 days after completion of radiotherapy the mass on the left side of the neck had regressed to scattered small nodules which were not measurable; on the right side regression had occurred to approximately one-third of the original size.

It is clear that considerable clinical investigation will be required to evaluate this method of treatment. While there is evidence, which formed the basis of this clinical trial, that cortisone modifies or suppresses the skin lesions produced by ultraviolet light in man [1] and by soft X rays in animals,[2] there is no existing evidence on the possible effect of such therapy on the radiosensitivity of tumours. Owing to the action of cortisone or A.C.T.H. on inflammation and œdema in the neighbourhood of the tumour, and on the stromal reaction during radiotherapy, it is probable that the effects may be considerable, and the value of the method depends on their favourable direction.

The danger of severe sepsis during hormone therapy, pointed out by Dr. Houghton and Dr. Walter, is probably greatest in cases of carcinoma of the lung, and may not present such a serious problem in other types of tumour.

The cortisone employed in this investigation was supplied by the Medical Research Council.

EFFECT OF OÖPHORECTOMY AND SPLENECTOMY ON MALIGNANT DISEASE

SIR,—In 1936 I published [3] a report of two cases of carcinoma in each of which both ovaries and the spleen had been removed; and I now take this opportunity to complete their clinical history.

The first patient, a woman aged 41, had had her uterus and ovaries removed 2 years previously for carcinoma of the uterus. When I saw her 2 years later, the disease had recurred in Douglas's pouch, and had extended to the bladder on the one side and the rectum on the other, with a considerable quantity of blood in both bladder and rectum. There was also extensive abdominal glandular infection.

I removed the spleen and gave her daily subcutaneous injections of splenic extract, beginning with a daily dose of 4 ml. and gradually reducing it to 1 ml. daily. During the time 4 ml. was given, the disease steadily got worse, and only after the dose had been reduced to 1 ml. and continued for 2 months was slight improvement noted. These injections were continued altogether for 3½ months with slight improvement. After they were stopped, the patient's condition steadily improved, and at the end of a year there was no sign of malignant disease. 16 years from the time her spleen was removed she died of coronary thrombosis with no sign of recurrence.

In the second case the result was not so satisfactory, for the patient died 5½ years after removal of both ovaries and spleen. For the first 4 months after the operation, the disease appeared to remain stationary; it then began to improve and continued to do so, till 10 months after her operation all traces had disappeared. She remained apparently well for 5 years, when symptoms developed pointing to involvement of the liver with some ascites. These symptoms gradually increased till she died 6 months later.

I did quite a number of operations similar to the second, but the result was always the same—death at varying intervals after removal of the spleen and ovaries.

Is there any possible explanation of why the result should have been so different in these two patients? The only one I can offer is the length of time between removal of the ovaries and of the spleen; in the first case the interval was 2 years, whereas both were removed at the same time in the other cases. I can offer no explanation why a late removal of the spleen, as against both ovaries and spleen at the same time, should have this effect, but it seems to me that in the first case some change takes place in the fluids of the body which is deleterious to the growth of malignant cells.

Cove, by Helensburgh. PETER PATERSON.

THE SENIOR REGISTRAR

SIR,—We agree with Mr. Leacock that the number of doctors of registrar or equivalent status, who are likely to compete for consultant vacancies, is greater than the figure we cited (April 18). We now know that senior registrars in their final year in the United Kingdom total more than 327. We could not include research assistants in our figures because of difficulty in obtaining accurate information, and we excluded university posts since each appointment of this type, if vacated by a man who has obtained a consultant post, leaves a gap which can conveniently be filled by an ex-registrar.

We also agree with Mr. Leacock's suggestion, in his letter last week, that in general medicine and surgery even the agreed senior-registrar establishment is not truly related to future prospects and should be reviewed. So far as the present generation of senior registrars is concerned, it is open to Mr. Leacock to suggest a *coup de grâce*; but we do not feel that under present circumstances there would be much grace about the coup, and certainly we are not in a position to recommend such a step as long as there are other methods of dealing with the problem.

We would point out, however, that while we are asking that the best of the present generation be given the opportunity of an extended tenure, we do so with the full knowledge that the improvement in each individual's chances will be only slight without parallel expansion of the consultant service. If our proposal is accepted, any senior registrar who seeks to continue must do so with his eyes open. All we can hope to do is to suggest means to this end for those who can see a real prospect of a consultant post in the future. We shall continue with our endeavours to make this a reality and not a mirage.

R. M. FORRESTER
Late chairman.
JOHN N. WALTON
Chairman, Registrars' Group, B.M.A.

DISORDERS OF MOTILITY OF THE SMALL BOWEL

SIR,—The valuable work of Professor Frazer and his associates to which Dr. Hawkins draws attention in his letter (April 18) was known to us. I do not believe, however, that the cases described by me (April 4) corresponded exactly to those discussed by Dr. Hawkins. The fault is perhaps mine for failing to clarify the distinction.

In a follow-up of any large series of patients who have undergone gastrectomy, cases of deficient fat absorption associated with anæmia and riboflavine deficiency are not infrequently encountered. Such patients do not suffer severe abdominal pain, and kymographic studies show a distinct lack of tone and a diminished small-bowel motility pattern. In addition, radiographic examination usually demonstrates dilatation of the jejunum. In the four cases I have described, however, severe griping abdominal pain is the patient's chief complaint, a pain which persists for upwards of one hour without relief. Kymography in three of these cases demonstrated increased intestinal tonus and irregular spasmodic contractions without any increased rate of passage of food in the gut. I would hesitate to suggest that the condition described is any more than a variant of the more typical deficiency pattern encountered either after gastrectomy or in the sprue syndrome. The clinical features are, however, sufficiently distinctive to allow separation of the two conditions.

Royal Appointment

Brigadier F C Hilton Sergeant, late R A M C, has been appointed honorary physician to the Queen in succession to Major General A J Beveridge, late R A M C

Scientific Film Association

A film appraisal meeting is to be held at St Bartholomew's Hospital Medical College, West Smithfield, London, E C 1, at 5 30 P M on Tuesday, May 12 The following films will be shown *Effect of Metallic Ions and Osmotic Disturbances of the Heart*, *Gastric Secretion*, and *The Mitral Valve* Medical students and doctors are invited

London Health Exhibition

On Monday, May 11, at 2 30 P M, at Woodberry Down Health Centre, Green Lanes, Stoke Newington Prof James Mackintosh will open an exhibition illustrating the health services available to the people of London The exhibition will be open daily from 10 A M to 8 P M till May 16 and the programme includes film shows talks, physical training displays, and cookery demonstrations

The Ministry of Food has published a new edition of the memorandum for doctors which sets out the arrangements for granting special rations and priority allowances of food to invalids and others needing special diets The revised memorandum, which is known as Med 2 (1953), replaces Med 2 (Revised 1950) Copies are being sent to all doctors in the United Kingdom, but additional copies can be obtained from the local food offices

CORRIGENDUM *Surgery of Varicose Veins*—Mr Rowden Foote's film (*Lancet*, April 25, 1953, p 858) runs for 28 (not 18) minutes

---

On April 18 the Harveian Librarian of the Royal College of Physicians appealed through our columns for a copy of the Harveian oration for 1849 which was needed to complete the college's collection of these orations We understand that the missing copy has been supplied by the president of the Royal College of Surgeons The Harveian Librarian is still seeking a portrait or photograph of Dr George Oliver of Harrogate and London, founder of the Oliver Sharpey lectures (see *Lancet* March 21, 1953, p 605)

Information about appointments in the Colonial Service is given in a new edition of a Government publication (*Appointments in Her Majesty's Colonial Service* H M Stationery Office Pp 130 3*s* 6*d*)

EXPERIMENTAL DATA

Dextran of various types has been infused into patients undergoing surgical operation. The observations reported have been made on five types of dextran whose molecular-weight distribution makes them of special interest. The first two types described were each given to 5 patients, the third type to 58 patients, the fourth to 22 patients and the fifth to 36 patients.

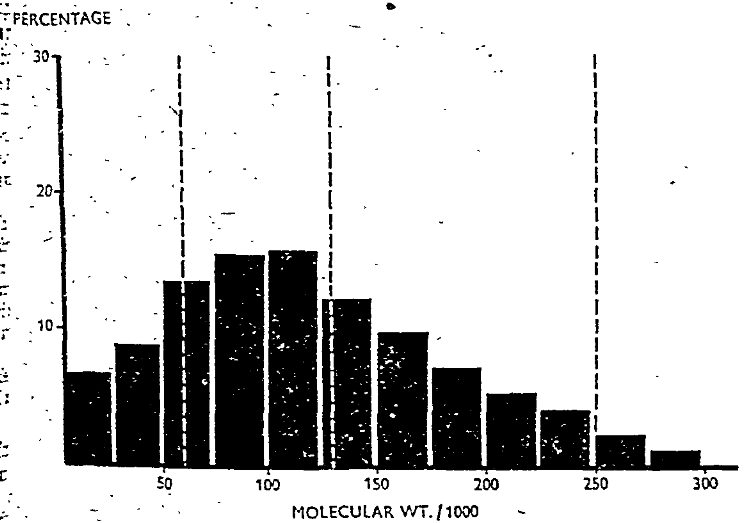

Fig. 2—Distribution of molecular weight of dextran as used by Bull et al. (1949).

To estimate the excretion-rate the patients' urine was collected in two batches: (1) for the first twenty-four hours after the start of the infusion; and (2) for from twenty-four to forty-eight hours after. Blood samples were taken before infusion and at five minutes, and six, twenty-four, forty-eight, seventy-two, ninety-six, and one hundred and twenty hours after the end of infusion.

Discussion of the techniques and problems of accurate estimation of the amount of dextran remaining in the circulation is beyond the scope of this paper.

To obtain a true value it is necessary to measure the blood volume at the time of taking each sample, and this is not always feasible in the postoperative patient. It has been found, however, that reliable results may be obtained by taking the five-minute sample as a reference level and applying a correction factor—0·9 in the case of the low-excretion types of dextran—to the later readings.

Patients who experienced severe hæmorrhage or with postoperative oliguria or other factors which might have influenced the results were excluded from the series. Patients who received blood or any other supportive therapy in addition to the dextran were likewise excluded.

In the cases reported the amount infused was two bottles—about a litre—of a 6% solution of the dextran under test in physiological saline solution.

The first type to be investigated was a standard material prepared by long hydrolysis and fractionation to remove any large molecules which might still be present. The molecular-weight distribution of this type is shown in fig. 1 as an equal-area diagram. Each block in the diagram has a molecular-weight range of 25,000, and the height of any block represents the amount of dextran in that particular range expressed as a percentage of the whole. As would be expected of material having a preponderance of small molecules, the excretion-rate was high—35% in twenty-four hours—and the blood level at the end of twenty-four hours was low, being 20% of the amount infused.

The distribution of the next type of dextran is shown in fig. 2. This standard material was similar in character to that reported by Bull et al. (1949), being prepared by short hydrolysis followed by fractionation to remove the large molecules. However, it still contained a small quantity of the molecular range we consider undesirably high. Because of the fewer small molecules the excretion-rate was reduced to 20%, but the twenty-four-hour blood level was only raised to 35%. This meant that during the first twenty-four hours after infusion more of the dextran was lost from the circulation than remained in it.

The observations made at this stage suggested that, to obtain a satisfactory twenty-four-hour blood level, a type of dextran must be made containing a much greater proportion of molecules in the middle range immediately above the diffusion threshold. It was also felt that the larger molecules should be completely removed. These requirements necessitated a re-design of the process of manufacture and the development of a large-scale method of intensive fractionation.

We have called material prepared by this method "narrow-fraction dextran" to distinguish it from that prepared by methods not involving intensive fractionation. We are aware that the purist physical-chemist may object to the designation on the grounds that the material contains molecules outside the desired range, but we are unrepentant.

The molecular-weight distribution of the third type of dextran (narrow-fraction A) to be investigated is shown in fig. 3. It will be seen that most of the material is in the molecular ranges close to the diffusion threshold. The excretion-rate was 11%, and the twenty-four-hour blood level was 47%, which was felt to be encouragingly close to the 50% considered to be the desirable minimum. This was achieved with narrow-fraction B (fig. 4) with an average twenty-four-hour blood level of 55%. This material had a slightly higher proportion of small molecules than the previous type, and the excretion-rate was in consequence raised to 14%. The final type investigated in this series, narrow-fraction C (fig. 5), had the highest blood level so far obtained, 68%, at twenty-four hours and also, at 8%, the lowest excretion-rate.

As would be expected, the material with the highest twenty-four-hour blood level is also the best maintained over longer periods. At the end of the five-day period about 20% of narrow-fraction C dextran remained in the circulation as opposed to less than 15% of narrow-fraction A and B.

CLINICAL DATA

Complete clinical assessment of the rôle of narrow-fraction dextran must depend on observations on a large

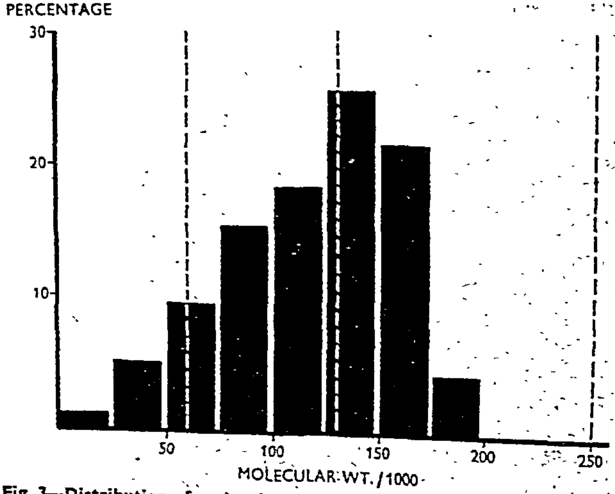

Fig. 3—Distribution of molecular weight of narrow-fraction A dextran.

number of cases of various types From study of about 120 cases in which narrow-fraction dextran has been used it is possible to make some general observations

Prophylaxis

The use of narrow fraction C dextran as an infusion for patients undergoing major surgical operations enables supportive therapy to be given in the simplest possible manner The infusion is started soon after the patient is anæsthetised and while he is still in the anæsthetic room The dextran is run in slowly—ten to twenty drops a minute—at first At the first sign of any fall in blood-pressure during the course of the operation the infusion-rate is increased By occasional adjustment of the drip it is possible to maintain the blood-pressure at a steady level through even the most severe operations

Since narrow-fraction dextran is retained in the circulation at an adequate level over the critical post-operative forty-eight hours, it is rarely necessary to continue the infusion after the operation has been completed This presents a considerable advantage, since it enables the drip to be taken down while the patient is still in the theatre Apart from the psychological effect—the patient recovering from anæsthesia to find an infusion in progress immediately fears the worst—he is not cluttered up with the paraphernalia of the infusion equipment, and the nurses are consequently spared complicated manœuvres in attending to him

Unless there is excessive loss of blood during the operation, narrow-fraction dextran is all that is needed The requirements for the prevention of shock are the maintenance of circulation volume and blood-pressure, reduction of the oxygen-carrying capacity of the blood by dilution with dextran is now of minor importance, because with the narrow-fraction material the total volume of the infusion required is far less than with the earlier standard material, which was rapidly lost from the circulation If there is severe hæmorrhage, blood may be given at the same time as the dextran It is an advantage to give blood and dextran simultaneously, rather than to replace the dextran by blood In some cases dextran has been more effective than blood in restoring a falling blood-pressure

Shock

If the patient arrives at the hospital with the shock syndrome already established, a sample of blood is taken for typing (see below), and a bottle of dextran is next infused as rapidly as possible A second bottle is given at a rate depending on the blood-pressure

Most of the patients in this series have responded adequately to the infusion of two bottles of narrow-fraction dextran, but occasionally a third bottle has been found desirable After the infusion of three bottles of dextran a bottle of blood should be given to prevent undue hæmodilution If further infusion is then necessary, dextran and blood may be given alternately

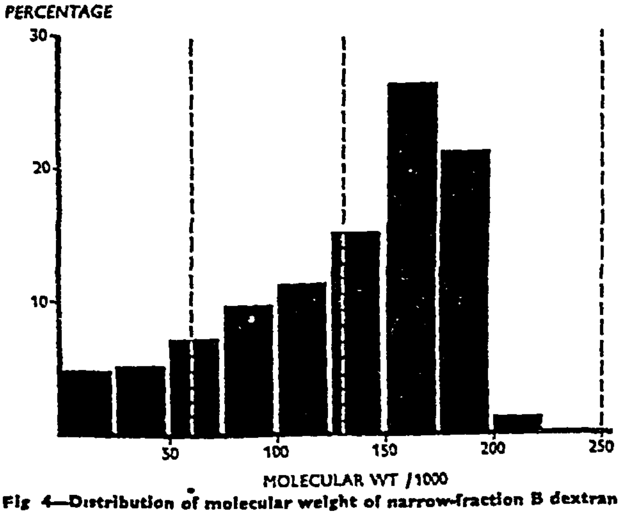

Fig 4—Distribution of molecular weight of narrow-fraction B dextran

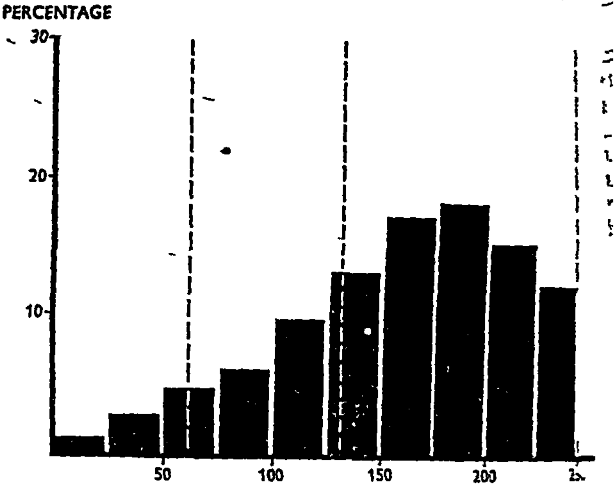

Fig 5—Distribution of molecular weight of narrow fraction C dextr

An inadequate number of cases of burns have been observed for any definite pronouncement to be made now Since the primary cause of loss of fluid from the circulation is effusion from the damaged capillaries of the burnt areas, it seems logical that the less easily diffusible material would be the better This, however, must be the subject of further investigation

Reactions

No reactions have been observed with any of the cases infused with narrow-fraction dextran in the surgical professorial unit at Manchester Royal Infirmary A mild rigor after the infusion of this material has been reported from one of the associated hospitals Since the incidence of reactions with a standard type of dextran containing molecules of a higher molecular weight than any of the narrow-fraction dextran used has been shown to be very low (Maycock 1952), any attempt to estimate the reaction rate must be left until several thousand patients have been infused

Other Observations

Many macromolecular substances, when present in the serum, have been shown to produce a pseudo agglutination which may make cross matching difficult for the inexperienced, and narrow-fraction dextran is no exception to this rule A routine blood sample to enable grouping to be done should therefore be taken before the administration of dextran In common with other types this dextran also has a pronounced effect on the erythrocyte sedimentation rate (E S R), which is increased for from three to five days after infusion Gronwall and Ingelman (1945) have shown that the E S R increased with the concentration of dextran, and Thorsen and Hint (1950) have shown that with a given concentration the increase depends on the molecular size Hardwicke et al (1950) have demonstrated a relationship between these parameters

Experiments are at present being made as a result of which it is hoped that it will be possible to obviate both the effect on the E S R and on the blood grouping

At one period during the investigation alarm was caused by the incidence of hæmatomata in patients in this series It was at first thought that this might be due to some hitherto unobserved effect on the bleeding time by dextran molecules of the range used when present in sufficient concentration It was then found that a common factor in all these cases had been the use of gallamine as a muscle relaxant Similar cases were then

THE NEED FOR A PHILOSOPHY OF MEDICINE *

Sir Russell Brain
D.M. Oxfd, P.R.C.P.

PHYSICIAN TO THE LONDON HOSPITAL AND THE MAIDA VALE HOSPITAL

The *Shorter Oxford Dictionary* gives a number of definitions of philosophy. The first is "the love, study, or pursuit of wisdom, or of knowledge of things and their causes, whether theoretical or practical." Later, philosophy is defined as "the study of the general principles of some particular branch of knowledge, experience or activity."

Philosophy in fact has slowly changed its meaning over the centuries: long ago its purpose was the pursuit of wisdom, but it has become increasingly preoccupied with technical problems of thought, until today philosophers are almost exclusively concerned with the process of knowing, and so little with knowledge that they would hastily disclaim any pretensions to be wiser than anyone else. With occasional partial exceptions, philosophy has lost its comprehensive outlook, and wisdom is above all comprehensive; indeed it now seems almost a paradox to say that only the comprehensive can comprehend. We do not ask with Job: "Where shall wisdom be found?" nor do we even lament with Omar that it yields such a disappointing harvest. The present generation would possibly be more inclined to agree with Blake that "the road of excess leads to the palace of wisdom." But perhaps, after all, wisdom is somewhat of an obituary virtue, more obvious in the dead than in the living, and more tolerable when sententiousness is safely silent and can no longer be embodied in a lecture. Is there indeed any substantial difference between the two definitions of philosophy which I quoted from the dictionary, for does wisdom really imply any more than a grasp of general principles, the ability to see the wood as well as the trees?

A philosophy of medicine, then, means the enunciation of general principles within medicine; but it also means something more, for it should include the criticism of medicine and its own general principles by means of the wider principles embodied in philosophy. This is a process which is going on in many fields of knowledge, notably in physics. One of the striking developments of thought in the present century has been the growth of scientific philosophy—i.e., the application of philosophical principles to science. This important task is one which can be carried out only by the scientists themselves, because the philosophers lack the necessary scientific training. At first sight it is rather surprising that this need has been so little recognised in medicine, where the opportunities are so rich; for we have no physician-philosophers to compare with the physicist-philosophers such as Eddington, Jeans, Planck, Dirac, and Schrodinger, nor with Russell and Whitehead who came to philosophy by way of mathematics. No doubt doctors are too fully occupied with their day-to-day work in applying the new discoveries of science to find time to discuss their more remote theoretical implications. Nevertheless I shall maintain that this need is real and urgent, and that, abstract though it may sound, a philosophy of medicine greatly concerns the welfare of our patients in many ways.

For this reason, though it is possible to discuss the question primarily in terms of abstract thought, I prefer to begin with practice; and I shall try first to show how a philosophy of medicine is necessitated by our practical needs. Since I am aiming at a comprehensive view, I must necessarily deal far too briefly with a number of aspects of the question, any one of which alone is important enough to justify far more discussion.

The Differentiation of Medicine

In order to understand how our present problems have arisen I must review certain of the recent developments of medicine; and, though in doing this I shall tell you nothing which you do not already know, I shall try to present the familiar facts as illustrating a single underlying principle. This is that the evolution of medicine during the last century has involved a process of differentiation, which has gone parallel with, and been intimately related to, the increase of knowledge. Two points need to be noted about this process: the first is that it has never been based entirely upon scientific considerations. Social and other factors, which from a scientific point of view were accidental, cut into it and profoundly influenced it. Secondly, the differentiation of medicine is reflected not only in the specialisation of the various groups of doctors, but in bricks and mortar, in the structure and the geographical arrangement of hospitals.

The time-honoured division between medicine and surgery was based, of course, upon a difference of therapeutic technique. Necessarily they overlapped—in diagnosis for example, and when a medical disorder developed into a surgical one, or conversely. Nevertheless the distinction remained a rigid one for centuries. The third great division of medicine—obstetrics and gynæcology—arose on an entirely different basis, for midwifery had its roots in a physiological function and its domain was demarcated by the appropriate anatomy. Gynæcology was an offshoot of the main stem. But because the basis of both was anatomophysiological—and, may one not add, also psychological?—obstetricians and gynæcologists became and remained both physicians and surgeons, and many will have known obstetricians who liked to be called "Doctor."

Increasing knowledge during the 19th century brought a new mode of differentiation into both medicine and surgery—the anatomical. Ophthalmic surgery was one of the first instances of this, its sphere combining disease of the eye as an anatomical structure with disorders of vision, which extended its scope into related anatomical structures such as the visual pathways in the nervous system. The contemporary development of neurology, dermatology, and otorhinolaryngology illustrates the same principle—that of differentiation on an anatomical basis; and, of course, many similar special branches of medicine and surgery have developed since. It must not be supposed that because I call the basis of these specialties anatomical they are not concerned with physiology. Of course they are: but the demarcation of their spheres of activity is anatomical, and they study physiology as the science of the functions of particular organs—an important point to which I shall return. The delimitation of all these branches of medicine and surgery was complete in hospital structure at an earlier stage than in medical practice; for special hospitals isolated patients suffering from diseases of the eye, ear, nose and throat, skin, and nervous system at a time when doctors interested in these subjects were usually still practising general medicine or surgery as well.

Meanwhile advances in science were creating new specialties based upon special techniques. The discovery of X rays established radiology as a diagnostic technique covering the whole field of medicine. This in turn gave birth to radiotherapy—also widely applicable; and the utilisation of other physical agencies, including the hands of the masseuse, for purposes of treatment, produced

---

* The Annual Oration delivered at the Medical Society of London on May 11, 1953.

CASE 2.—A woman, aged 48, whose diabetes had been diagnosed for six years but poorly controlled by diet and insulin, complained of pain and swelling in the thighs

Examination showed the reported swellings to be prominences of normal tissue lying between areas of atrophic muscle These were circular about 3 in in diameter, overlying each iliac crest and lying behind the tensor fasciæ latæ muscles Less well defined areas lay in the upper thirds of each thigh A further lesion 1 in in diamter was present in the right triceps brachialis muscle Physical examination was otherwise normal

Insulin had usually been injected into the thighs, seldom in the arms, but not into the buttocks

CASE 3.—A woman, aged 46, who had been in satisfactory diabetic control on diet and insulin for ten years, noticed weakness and wasting of the thumbs for eight years, loss of flesh in the arms for five years, and in the right buttock for a year

She was found to have circumscribed areas of atrophy of the muscle and fat in the following sites the right masseter muscle, the biceps muscle of one arm and the triceps muscle of the opposite arm, the right buttock, on the natal fold These were such that the examining finger sank into them to the depth of bone The short adductors of the thumbs were also wasted. She also showed a tabes like neuropathy the Wassermann reactions of the blood and of the cerebrospinal fluid being normal

CASE 4.—An obese female, aged 66, with poor control of her diabetes by diet and insulin, had a deep area of atrophy of fat and muscle, about 1 in in diameter, in the right deltoid muscle The deltoid and triceps muscles were weak in this arm and the triceps jerk absent Neurological examination was otherwise normal

The right hand was always used for insulin injection, which was normally into the left arm

CASE 5.—A woman, aged 69, who was admitted to hospital after cerebral thrombosis, had had diabetes for eleven years, adequately controlled with diet and insulin

Examination showed a right spastic hemiparesis with moderate dysphasia and comprehension defect Sensory examination gave uncertain results. There were three discrete areas of muscular atrophy in the left thigh, immediately overlying the femoral artery in Scarpa's triangle (fig 2), was a roughly circular area 3 in. in diameter; a linear lesion, 2 × 1 in., ran below the left deltoid, and a circular area, 1 in. in diameter lay in the right triceps brachialis muscle

The patient and her daughter normally coöperated in injecting insulin and invariably used the arms

CASE 6.—A woman, aged 68, who had controlled her diabetes moderately well for eight years with diet and insulin, complained of aching pains in the legs for years and of weakness in the legs since a bowel disturbance with mild ketosis a month before

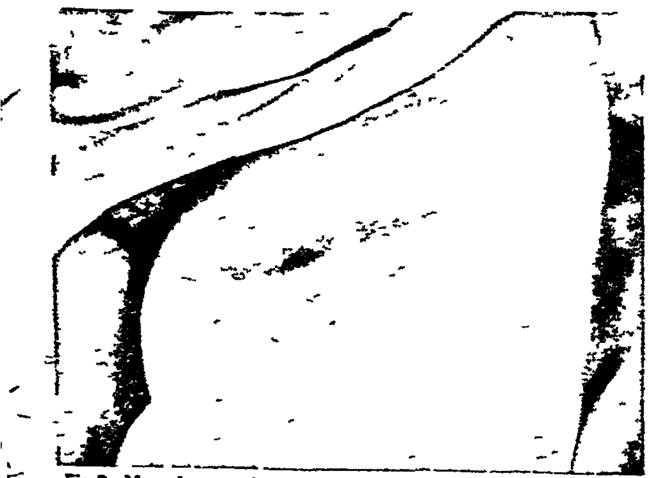

Fig 2—Muscular atrophy over Scarpa's triangle in left thigh (case 5)

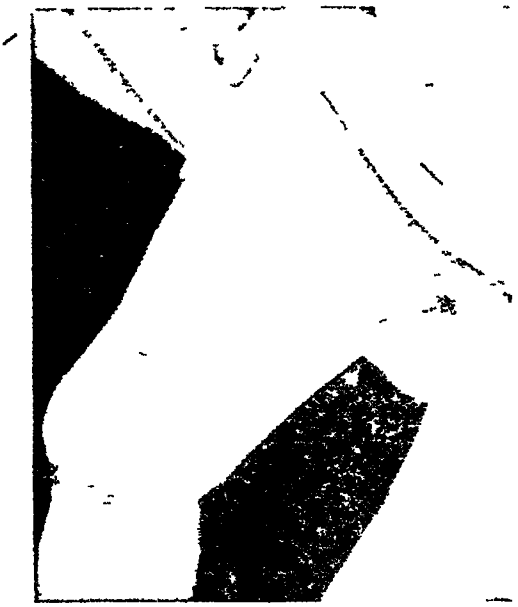

Fig 3—Muscular atrophy on inner aspect of right thigh (case 6)

Examination showed areas of muscular atrophy $^1/_2$ to 1 in in diameter, on the inner aspects of each thigh and the outer aspect of the left thigh (fig 3)

The patient normally injected insulin into her arms and insisted that only on three or four occasions had she had injections in her legs

DISCUSSION

These localised areas of muscular atrophy in diabetics are distinct from insulin atrophy. In the present cases the usual sites of injection have been spared, and the characteristic induration found with insulin lesions has been absent The atrophy has been found in unusual places for injection, in case 3 injection in the situation of the lesions may be regarded as impossible I have not seen any similar lesion in a patient not taking insulin, but in the pre-insulin era apparently similar lesions were reported by Bernard and Fere (1882), Auche (1890), and Pitres and Marchand (1917)

Joslin (1946) described ectopic lipodystrophy in the face, breast, and submental regions A photograph published by Rudy and Epstein (1945) appears to be of a lesion of the kind described here, and Rudy (1945) expressed the view that "occasionally isolated muscle atrophy may be mistaken for insulin atrophy" Yohalem and Pollack (1949) found no evidence of insulin atrophy remote from the site of injection

Panatrophy (Kinnier Wilson 1940) has not been described in diabetes, and in panatrophy the skin is abnormal, a feature absent in the present cases

Half the cases described showed neurological abnormalities, but the muscle lesions did not correspond to any nerve distribution The existence of separate diabetic lesions in one patient is a common chance occurrence

SUMMARY

Six cases of localised areas of atrophy of muscle and subcutaneous tissues in diabetes are described

The condition probably represents a specific diabetic lesion and is independent of insulin lipodystrophy.

the specialty of physical medicine. But during the last hundred years medicine has been cross-cut by a quite different differentiating factor—namely, the social implications of certain kinds of disease. Those of the mentally sick who were dangerous or offensive to others had long been segregated: with the growth of law and humanitarianism such confinement had to fulfil legal requirements, and the mental hospital system brought into existence a peculiarly limited specialty, presided over by a Government department, the Board of Control. Somewhat similar social considerations led to the segregation of patients suffering from infectious diseases. From this sprang the fever hospitals, the hospitals and clinics for venereal diseases, and the tuberculosis sanatoria. Other specialists who were differentiated by social need were the experts in industrial medicine and hygiene, the school medical officer, the medical officer of health, and the medical Civil Servant in Whitehall.

All these are instances of the differentiation of medicine. Before I consider the advantages and disadvantages of this process let me draw attention to the evidence that for some time now a reverse process of re-integration has been going on. Since the fundamental division was that between medicine and surgery, the most significant reversal of this process is to be found where medicine and surgery have drawn together again. This is the result of a number of factors, especially increasing knowledge of physiology, pathology, bacteriology, and pharmacology, and also increasing specialisation. In many fields the surgeon has drawn nearer to the physician and, reciprocally, the physician has become more of a surgeon. For the surgeon, concentrating his attention increasingly upon disorders of function, is tending to become an operating physician. At the same time the physician, working in much closer collaboration with the surgeon, has had to acquire a greater knowledge of the technique of surgery, even though he never practises it himself. Hence, for example, in gastro-enterology, chest diseases, cardiology, neurology, and to some extent psychiatry there is a considerable ground which is common to both the physician and the surgeon.

A similar fusion of previously separated interests has occurred in the diagnostic field. As the knowledge within a specialty has increased, its demand upon diagnostic radiology has similarly became greater, and it has been found advantageous for cardiologists, chest physicians, and orthopædic surgeons, amongst others, to do some at least of their own diagnostic radiology. This has led to further increases in knowledge, and it has not meant the withdrawal of this specialised work from the radiologist; but, on the other hand, the new knowledge gained has often led to the development of fresh diagnostic techniques which can only be carried out by the physician or surgeon and the radiologist in collaboration. A variant of this process is to be found when the radiologist has himself specialised in a particular branch of medicine or surgery and has brought the knowledge he has thus gained to the enrichment of his radiological technique, as has happened, for example, in neuroradiology.

A quite different method of re-integration of medicine has taken place when a general physician, instead of endeavouring to comprehend as his province all the specialties at all ages, has limited the demands of such generalisation by specialising in patients of a certain age-group. Thus, the pædiatrician at one extreme of life, and the geriatrician at the other, reassert the claims of generalisation and its comprehensiveness in respect of many specialties. Finally, the increasing collaboration between physician and surgeon in various spheres is only an example of a more general tendency towards team-work between different kinds of specialists, which is now a commonplace in diagnosis and treatment.

The Effects of Differentiation

The evolutionary process which I have called differentiation in medicine has produced such a great increase in our knowledge and therapeutic powers that its benefits are too obvious to need elaboration now. Indeed their very magnitude has tended to obscure the price which we have had to pay, and are still paying, for them. The separate development of psychiatry and neurology in this country is an example of this. As I have already pointed out, psychiatry here developed in the remote isolation of the mental hospital, while neurology flourished in two special hospitals and later in the neurological departments of general hospitals. An early opportunity to bridge this gap was missed when the pioneer work of Ferrier, carried out in a mental hospital, failed to develop into any permanent relationship between neurology and psychiatry. The progress of English psychiatry might have been advanced by at least half a century if the genius of Hughlings Jackson could have found disciples in the mental hospital world. As it was, alienists, as they were called, remained caretakers of the incurably insane, while minor mental disorders, and minor degrees of graver ones, were treated chiefly by neurologists. There remained a few consultant psychiatrists outside the mental hospitals, in which they had chiefly gained their experience, who were called in to certify patients. As a consequence the psychological and neurological aspects of mental disorder, biologically indissoluble, were forcibly kept apart; and the new ideas of analytical psychopathology and therapy, when they reached this country after the first world war, were taken up and developed independently of both psychiatry and neurology.

A drawback of a similar kind arises from the isolation in special hospitals of patients suffering from infectious diseases, and the development within this field of a specialty solely concerned with a single disease of a single organ—pulmonary tuberculosis. However important the fact of infectivity may be for a community, it has led to what is otherwise a quite artificial separation of certain diseases from the main body of medicine—diseases which in general, and even in spite of their being infectious, may have less in common amongst themselves than they have individually with other diseases treated in general hospitals. Both general medicine and the artificial specialties of fevers and tuberculosis have been impoverished by this separation, and the disadvantages have extended also to nursing.

The division of medicine and surgery into specialties based upon anatomical systems, though it has produced a rich and ever-growing harvest of fresh knowledge, has led also to the existence of gaps between such specialties and the general body of medicine and between one specialty and another, the effect of which upon medical science I shall consider in more detail later. It has also created two major problems which confront us today, in medical education and general practice.

For many years the student has had to obtain a limited amount of his medical teaching and experience in institutions outside his teaching hospital—for example, courses of lectures and demonstrations at mental hospitals and fever hospitals. This was not only geographically inconvenient but inevitably caused the student to feel that mental disorders and infectious diseases were events outside the run of ordinary practice, and in which he seemed likely to be concerned only with diagnosis and disposal. These, however, had been regarded as separate branches of medicine so long that their relative isolation was taken for granted. Until after the first world war, however, there were very few special departments in the teaching hospitals. Since then so many have come into existence that the student now has to obtain much of his experience and teaching in depart-

Long and Miles (1950) found that cortisone and adrenocorticotrophic hormone (A C T H) diminished experimental tuberculin hypersensitivity in the guineapig Postulating a possible analogy between this form of allergy and the tissue reaction in rheumatoid arthritis, Long et al (1951b) suggested that other factors influencing experimental tuberculin hypersensitivity might also influence arthritis in man They described several such factors (Long et al 1951a and b, Fisher et al 1951, Cornforth and Long 1952) In man we found that cortisone and A C T H diminished the tuberculin reaction more conspicuously than other inflammations studied, and we considered the possibility that this reaction might reflect the nature of the disease process in rheumatoid arthritis (Lovell et al. 1953) We therefore tried to discover if some of the factors shown by Long and his colleagues to effect experimental tuberculin hypersensitivity influenced rheumatoid arthritis, we also studied their effect on the tuberculin reaction in man We report these studies here

Long et al (1951a) suggested that, in guineapigs, the desensitising action of cortisone and A C T H was mediated by an indirect effect on the metabolism of ascorbic acid In laboratory animals deficient in ascorbic acid but not clinically scorbutic, fed on a synthetic pelleted diet, sensitivity to tuberculin was high and could be diminished by giving ascorbic acid but not by giving the hormones The hormones did not enhance the desensitising action of ascorbic acid If tuberculin sensitivity in the guineapig and rheumatoid arthritis in man were analogous, and the mode of action of cortisone and A C T H was comparable in the two conditions, a deficiency of ascorbic acid might be expected to enhance the inflammation in rheumatoid arthritis and at the same time to diminish the responsiveness of the disease to the hormones In a state of depletion of ascorbic acid, treatment with ascorbic acid might diminish the activity of the arthritis In our first study we examined these possibilities

Our second study was of the effects on rheumatoid arthritis and tuberculin reactions of two substances which modified experimental tuberculin hypersensitivity in the guineapig—namely, glucose-1-phosphate and lysergic acid diethylamide (L S D) Cornforth and Long (1952) found that tuberculin sensitivity in guineapigs was reduced by a subcutaneous injection of glucose 1 phosphate 0 01 mg per kg body-weight and by L S D 0 00018 mg per kg body-weight We are not aware of any reports of the effects of glucose 1-phosphate in man The effects of L S D both in normal and in psychopathic patients have been reported by several workers—e g, Rinkel et al (1952) It causes transient mental changes and disturbances in the autonomic nervous system The effects have sometimes been observed with doses as small as 0 02 mg , and 0 04–0 1 mg is reported to be active in most cases, though individual variation in responsiveness seems to be great

Methods

Ten patients studied had active rheumatoid arthritis, and one had polyarteritis nodosa with predominant involvement of the joints All were treated by rest in bed, controlled exercises, and, when necessary, splinting of acutely inflamed joints

All the patients received acetylsalicylic acid ('Disprin'), gr 30–60 daily, and sometimes tab codeine co *B P* We have found in man that tuberculin reactivity is unaltered by salicylates, and Long (1952) has found salicylates to be without effect on tuberculin sensitivity in guineapigs Salicylates do not modify the beneficial therapeutic effects of cortisone and A C T H We did not therefore feel justified in withholding these analgesics Their use, however, implies a more severe test of factors possibly giving mild relief of symptoms in arthritis than would have been imposed if they had been withheld,

TABLE I—SUMMARY OF RESULTS OF ASCORBIC-ACID STUDIES

Patient	Study	Régime	Duration in weeks	Blood ascorbic acid (mg per 100 ml)	Course of arthritis
1	A	(*a*) Ordinary diet		0 3	
		(*b*) Scorbutic diet	11	0 3→<0 1	
		(*c*) Scorbutic diet + 1 g ascorbic acid daily	5	2 1–2 5*	
		(*d*) Scorbutic diet + 1 g ascorbic acid daily + cortisone	1½	1 9	
		(*e*) Ordinary diet + ascorbic acid 1 g daily	2	2 1	Relapse lasting 2 weeks
	B	(*a*) Scorbutic diet	10	2 1→<0 1	Fluctuating
		(*b*) Scorbutic diet + cortisone	3 }	<0 1	Conspicuous improvement
		Scorbutic diet + A C T H	3½ }

* Attained with 3 g ascorbic acid † Attained with 2 5 g ascorbic acid

ments which, except that they are under the same roof, are sometimes almost as much differentiated from the general body of medicine as the mental hospital and the fever hospital of the old days. The problems which this creates for medical education are becoming well recognised. Moreover, the more complex and difficult medicine becomes, the greater the tendency to send patients who constitute obscure diagnostic problems to centres where the necessary investigations can be carried out, and except for the special hospitals these are almost invariably at teaching hospitals, which in consequence receive a disproportionately large number of rare and difficult cases. Then, as the number of special departments increases, the time which the student can spend in each of them necessarily grows less, so that the question arises whether periods of a month or six weeks spent successively in a number of special departments possess the same educational value as three months, or longer, spent on individual medical and surgical firms. Another teaching drawback arises from the fact that a student attending a special department deals with patients who have already been to some extent diagnostically sifted, so that the curriculum contains less opportunity for him to meet the situations which will confront him in practice, when he has to examine a patient for the first time without any clue as to the system affected and not even knowing whether the condition will turn out to be medical or surgical. Finally, it is widely felt that the increase in our detailed knowledge of individual anatomical systems makes it increasingly difficult to present the student with a concept of the patient as a whole, a point to which I shall return.

But, after all, most students are being educated for general practice, and the differentiation of medicine, which I have been tracing, has created problems for general practice which need to be solved not only for their own sakes, but also because unless we know what should be the future work of the general practitioner we are in no position to educate students for general practice. The effect of the increasing complexity of medicine, particularly of its diagnostic and therapeutic techniques, upon general practice is now so widely recognised that I need not elaborate it: it has led to an overemphasis on the hospital at the expense of the general practitioner, since at present it is only at the hospital that many investigations and the more elaborate treatments can be carried out. It is no part of my present purpose to say what could, or should, be done about this. I merely mention it as one of the by-products of the process of differentiation.

Finally, just at a time when we need all our energies to cope with these fundamental questions, so important for the welfare of medicine as an art and a science, political action has confronted us with an equally difficult set of problems arising out of the transformation of the organisation of medicine in this country. Although the two may at first sight appear independent, I believe that they are closely interlinked. Some reorganisation of medicine, whatever one may think about the precise form it took or the rate at which it was carried out, was necessitated by the very changes in medical science which we have been considering. But we cannot hope to solve the problem of medical organisation until we have discovered the principles upon which medicine should be organised—in other words, until we possess a philosophy of medicine. This cannot be supplied by politicians nor by Civil Servants, but only by ourselves; and until we have it we shall have no adequate defence against political empiricism and administrative bureaucracy.

A Philosophy of the Organism

What, then, should be the basis of a philosophy of medicine? Medicine is a branch of biology, and I believe that its philosophy should be based upon a re-examination of the conception of the living organism as a whole. I have pointed out how large a part differentiation has played in the evolution of medicine during the last hundred years. Sherrington (1947) quotes with approval Herbert Spencer's dictum that integration must keep pace with differentiation, but the same thing was said 80 years ago by that other great neurologist, Hughlings Jackson (1932), himself a disciple of Herbert Spencer. On this very occasion, Hughlings Jackson, delivering the Society's annual oration in 1877, said:

> "As scientific medical research goes on, there is greater specialisation of investigation, just as, in the development of society, there is that continually increasing specialisation, called division of labour. This being so, all the more need is there that there should be greater integration, just as along with division of labour there is need for coöperation of labourers. . . . There is no harm in studying a special subject; the harm is in doing any kind of work with a narrow aim and a narrow mind. Differentiation of medical investigation has led to results of inestimable value. If, in the smallest degree, I succeed in furthering the integration which should quickly follow this necessary differentiation, I shall feel that my address will be of some little value."

If Hughlings Jackson, with foresight in this as in so much else, recognised that need then, how much more necessary is it today that we should achieve an integrative view of the human organism; and this, I believe, must find its applications at the physiological, psychological, and social levels of thought.

Let us first consider the physiological. Visual form exercises a highly determining effect upon our thinking, and no doubt that explains why medicine has tended to divide the body into anatomical organs upon which special branches have been based. Thus, the cardiovascular system, the nervous system, the urinary system are all clear-cut anatomical structures which can be neatly dissected from the rest of the body. We recognise, of course, their physiological aspects, or functions; but we tend to regard functions as secondary or subordinate to form, and this is reflected in our way of speaking, for we speak of the functions *of* a particular organ. What, we ask, does it do? This use of words suggests that there is something, an organ, which exists in some way independently of what it does. This is a perfectly permissible way in which to describe a motor-car. The function of a motor-car is to move from one place to another, but the car continues to exist in the same form when it is at rest and not performing its function. This is not true, however, of the organs of the body; for during life an organ can be separated from its functions only by an artificial abstraction. In the living organism form and function are two aspects of the same thing.

Our tendency to look upon function as subordinate to form has had far-reaching consequences, for this makes it difficult both to think of functions which cannot be fully described as the functions *of* particular organs, and also to conceive of the organism's functioning as a whole.

The American philosopher John Dewey has described the evolution of scientific thought in a way which has, I believe, fertile applications to medicine. Dewey and Bentley (1949) distinguish three historical stages in the development of our ways of explaining the phenomena which we observe. The first is the stage of *self-action.* The behaviour of a body is held at this stage to be self-explanatory: it behaves as it does because that is its nature. The next stage is the stage of *interaction* in which the behaviour of bodies is explained by their mutual relationship, which nevertheless is regarded as leaving each of them essentially unchanged. The third stage is the stage of *transaction.* In this stage we are dealing with an event which involves several constituents for salicylates afford some such relief However, it was against the more conspicuous effects of cortisone and A.C.T.H. treatment that we wished to measure an effect, if any

The arthritis was assessed at least twice a week in the long studies, and daily in the shorter ones, by measurements of heat, swelling, tenderness, and functional capacity of the joints To the patients treated with glucose-1-phosphate and L.S.D., dummy preparations were usually administered for up to 14 days before treatment

Cortisone (Merck) 200 mg daily was given orally in case 1 and by intramuscular injection in case 2 A.C.T.H. (Armour) 100 mg daily was given by intramuscular injection Ascorbic acid (Roche) was given orally

When a scorbutic diet was given, all the cooking was done in copper vessels Fruit, fruit juices, and vegetables were not allowed All the milk was boiled. Potatoes were boiled, mashed, and kept hot for at least an hour before being served Ascorbic acid in whole blood was measured at least once a week by the method of Roe and Kuether (1943)

The α-D-glucose-1-phosphate was prepared by Roche Products Ltd as a solution containing 50 mg of the dipotassium salt per ml The preparation was confirmed by Dr D A Long to be active in reducing tuberculin hypersensitivity in guineapigs Intramuscular and subcutaneous injections caused intense pain this could be mitigated by mixing the solution with procaine hydrochloride, but such a mixture was found by Dr Long to be inactive in the guineapig The glucose-1-phosphate was therefore given intravenously, by intermittent injections, or by continuous intraveonous drip in physiological saline solution The doses ranged from 4 to 800 mg. daily

Lysergic-acid diethylamide was supplied by Sandoz Products Ltd both as a powder and as a liquid Because of its instability, solutions made from the powder were freshly prepared every 5 days, fresh ampoules of liquid were opened for each dose The drug was given by mouth in about 30 ml of water before breakfast Doses ranged from 0·005 to 0·1 mg daily.

Tuberculin reactivity was tested by intradermal injections of serial dilutions of purified protein derivative (P.P.D.); as described by Lovell et al (1953) In patient no 3, the tests were made at intervals of 1–2 weeks In the other cases comparisons were based on between one and four tests done before and during treatment

Eosinophils in capillary blood were usually counted twice weekly and erythrocyte sedimentation rates (E.S.R.) were measured once a week

Results

ASCORBIC ACID

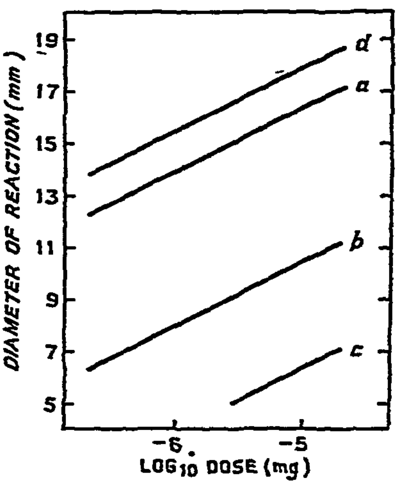
The results are summarised in table I

Patient 1 —Female, aged 34 Active rheumatoid arthritis for 8 months had involved almost all joints. During 11 weeks on scorbutic diet the arthritis improved. When the patient was saturated with ascorbic acid, the trend of improvement (already established) continued, and later there was a conspicuous clinical response to cortisone During a subsequent 10 weeks on scorbutic diet the arthritis fluctuated in severity, but there was no definite trend in its course While the patient was still on scorbutic diet the response to cortisone was again conspicuous and the improvement was sustained during a course of A.C.T.H.

Patient 2 —Female, aged 17 Active rheumatoid arthritis for 2 years affecting fingers, hands wrists elbows, and knees During 9 weeks on scorbutic diet the rheumatoid arthritis fluctuated in severity, but no definite trend was discernible The therapeutic response to cortisone when the patient was depleted of ascorbic acid appeared as full as an earlier response induced when there was no depletion. The disease responded to A.C.T.H. during the 13th to 15th weeks of scorbutic diet Saturation with ascorbic acid after 19 weeks on scorbutic diet, and subsequent return to full diet caused no appreciable change in the course of the disease

Patient 3 —Female, aged 50 Rheumatoid arthritis for 20 years Active inflammation in hands, wrists, right hip, and both knees During 9 weeks on scorbutic diet there was no change in the arthritis which could be attributed to this régime, nor was there one when the patient was saturated with ascorbic acid When the patient was saturated with ascorbic acid the symptoms were improved while A.C.T.H. was given

Tuberculin reactions were studied in patient no 3 At the beginning of the scorbutic diet, P.P.D. solutions weaker than 0·2 mg per ml did not evoke a response and this solution caused a lesion of only 10 mm diameter After a month's scorbutic diet, when the blood-ascorbic-acid level had fallen to about 0·1 mg per 100 ml, the reactivity was increased, a solution of 0·002 mg per ml giving a response just short of necrosis Tests with serial dilutions were made thereafter with 0·0002, 0·00002, and 0·000002 mg per ml (see figure) The reactivity was high when the blood-ascorbic-acid level was less than 0·1 mg per 100 ml, it fell when the patient was saturated with ascorbic acid and it fell further when A.C.T.H. 100 mg daily was given After A.C.T.H. was stopped reactivity rose to approximately the same level that was attained in the scorbutic state, though now the patient was still saturated with ascorbic acid



Patient 3.—Calculated mean parallel regressions of diameters of reactions on log dose of P P D injected during (a) ascorbic acid depletion, (b) ascorbic-acid saturation (c) A.C.T.H treatment, (d) after A.C.T.H For differences between (a) and (b), $0{\cdot}02 < P < 0{\cdot}05$ (b) and (c) $0{\cdot}05 < P < 0{\cdot}1$ and (c) and (d) $0{\cdot}01 < P < 0{\cdot}02$

Conclusion —Rheumatoid arthritis was uninfluenced by ascorbic-acid depletion or saturation, nor did these factors appear to influence the therapeutic effects of cortisone and A.C.T.H. In one patient reactivity to tuberculin increased during depletion of ascorbic acid, decreased after saturation, and decreased still further when A.C.T.H. was given When A.C.T.H. was withheld the reactivity to tuberculin rose to a level comparable to that attained during the period of ascorbic-acid depletion

GLUCOSE-1-PHOSPHATE

Patient 4 —Male, aged 47 Active rheumatoid arthritis for 3 years Main disability now due to inflammation in the knee-joints Glucose 1 phosphate 500 mg in 1 litre of physiological saline solution was given daily for 8 days by intravenous drip Each infusion lasted 12–16 hours There was no modification of the arthritis, which had improved conspicuously in the first 8 days of cortisone administration a year earlier Tuberculin reactivity was not changed significantly (table II), though it had been reduced about 100 fold during previous cortisone treatment (case 6 in paper by Lovell et al 1953)

Patient 5 —Male, aged 56 Active rheumatoid arthritis for 6 months involving mainly fingers, hands, wrists, and knees Received six intravenous injections of glucose-1-phosphate in doses of 10, 20, 50, 100, 200, and 200 mg There was no subjective or objective change in the arthritis Injections of 100 and 200 mg caused rigors owing to a pyrogen in the solution injected which cannot be treated in isolation from the event or from each other.

The characteristic feature of our present epoch in medicine is the growing significance of the idea of transaction. Many of the most important things that happen in the body can no longer be explained simply as the result of the interaction of two or more organs, but require the conception of a dynamic transaction which itself integrates the activities of the organs. Let me illustrate this. The electrolyte balance is equally vital to the life of the organism, and to the activity of all the tissues. The behaviour of the electrolytes in the body is the result of a complicated set of transactions involving the intake of fluid and salts, exchanges between the blood and tissues, the secretions of the suprarenal cortex, the excretory function of the kidneys, and many other factors. In these processes the constituents which I have mentioned are themselves affected by what goes on. We are here dealing, therefore, not with the interaction of unchanging objects like billiard balls, but with events which can only be expressed in transactional terms. In other words, though physiology and pathology have to take account of what is happening in individual organs, the transaction as a whole is the more important and unifying factor.

It is easy to find examples of the importance of the transactional view in every department of medicine. Hypertension due to unilateral renal damage, as Wilson showed in his recent Oliver-Sharpey lectures, is the outcome of the interplay of the two kidneys (each of which behaves differently), the suprarenal cortex, the electrolyte balance, and, of course, the cardiovascular system; and there are probably other unknown factors concerned. The bones, so hard and firm that they positively symbolise rigidity, are maintained by a continuous metabolic give-and-take which involves the dietary consumption of calcium and vitamin D, their absorption from the intestines, the power of the kidneys to eliminate calcium or to withhold it, and the influence of the parathyroids upon the whole. Hence it is equally artificial to describe renal rickets as a disease of the bones or as a disease of the kidneys, and the simplest fracture needs to be considered not merely as a response of a rigid structure to stress, but as possibly reflecting dietary insufficiency or defective metabolic function. Ogilvie (1953) has recently pointed out that there are at least four varieties of duodenal ulcer which differ in their ætiology: in other words, they are the outcome of the disorder of different kinds of bodily transaction; and it is possible, indeed that even pathologically identical peptic ulcers in different individuals are the result of different kinds of transactional disorders depending upon the different constitutions of the sufferers. If so, we are not entitled to infer, even from a common pathology, a common ætiology. The discovery of the first vitamin, an "accessory food factor" essential to health, was deceptive in its simplicity, but it introduced us to a biochemical world of astonishing complexity. Not only have we to take into account dietary intake, absorption, storage, and delivery of vitamins to the tissues, but in the tissue cells themselves the vitamins are integrated into most complicated chemical processes. Lack of vitamins may generate toxins: toxins may impair the utilisation of vitamins; and we are still far from understanding the full range of the interrelationships of vitamins with the endocrine glands. The importance of hereditary factors in the ætiology of disease is increasingly recognised, and transactional approach seems essential if we are to interpret the interplay of genetic endowment with the environment of the individual and his own initiative in dealing with both.

Returning, now, to the relation between form and function, we see that the units with which the doctor has to deal are not individual organs, carrying out particular functions, but highly complex functional transactions which can only be properly understood as functions of the organism as a whole. The visual form of an organ is a deceptive unity, and to ask what are the functions of the suprarenal is an examination question at a level of scientific thought which is in reality outmoded. The suprarenal produces a variety of chemical substances which influence the circulation, the electrolyte balance, sexual activity, and many other functions of the body; but it has only a geographical unity, like that of a factory which turns out parts for aeroplanes, vacuum cleaners, and mowing-machines. Our emphasis upon the individual organ arises partly from the dominant influence of visual form upon our thinking, but even more perhaps from the fact that so much of our time, whether as physicians or surgeons, is spent in dealing with what we call disease of an organ; but by the time an organ is diseased we are looking at the end-results of the breakdown of a complex set of transactional functions in which that organ is normally involved.

The transactional view shifts the emphasis in space from the diseased organ to the functional disorders of which it is a manifestation, and in time from the stage at which the organ is already diseased to the earlier stage at which the functional disorder has not yet led to permanent structural change. For example, it transfers attention from myocardial infarction to those unknown transactional disorders which produce atheroma, and which, in particular cases, determine its predominantly selective incidence upon the coronary arteries. Research has thus to turn from the simple and tangible—the organ which is literally tangible at operation or autopsy—to the complex intangible and ever fluctuating interplay of functions.

Medicine and the Mind

There is one sphere of thought in which the relationship between form and function raises quite peculiar difficulties, but is of unique importance—I mean the body-mind relationship. It is a curious paradox that at a time when the influence of the mind upon the body is more generally and profoundly recognised than it has ever been before, the predominant philosophies of the age regard mind as an outmoded concept. Today there are philosophers who make their living by expounding the non-existence of their own minds, and there are others who seem to regard mind as a slight logical indecency—a word which, though it may slip out now and again, must be hastily apologised for. I do not propose now to discuss in detail the age-long controversies which have raged, and still rage, around this topic.

There are two reasons why the body-mind relationship assumes great importance for a philosophy of medicine. The doctor has unique opportunities of observing the correlations which exist between states of mind and states of body, and which range from the broad experiences of everyday practice to the more precise studies of the neurologist and psychiatrist. These observations provide data which any philosophical theory of the relationship between body and mind must take into account. But, in addition, such a philosophical theory is of great practical importance for us as doctors; for until we understand better than we do the logical relationship which exists between our description of states of mind and our account of their corresponding neurophysiological states we shall not be able to think clearly about the way in which we ought to speak of states of the brain causing states of mind and conversely.

Pragmatically, as practising doctors, we do believe in the mind and we do assume a two-way relationship between mind and body. We accept the fact that when spirochætes attack the ganglion cells of the cerebral

Patient 6.—Male, aged 46. Rheumatoid arthritis for 7 years, and a severe relapse for past 3 months with active inflammation in fingers, hands, shoulders, hips, and knees. Glucose-1 phosphate 100 mg. was given intravenously twice daily for 4 days and 200 mg. twice daily for 3 days. There was no subjective or objective change in the arthritis and no significant change in tuberculin reactions (table II).

Patient 7.—Male, aged 52. Polyarteritis nodosa for 5 years, involving mainly the joints and skin. A maintenance dose of cortisone 50 mg. daily was incompletely suppressing the arthritis, which was most conspicuously active in wrists and knees. Intravenous glucose 1 phosphate 1 mg. was given four times daily for 1 day, 100 mg. for 3 days, and 200 mg. for 3 days. There was no subjective or objective change in the arthritis, though, when the treatment was stopped, there was relief of pain with objective improvement 4 days after the dose of cortisone had been increased to 100 mg. daily.

Conclusion.—In the doses used glucose-1-phosphate did not influence the course of the arthritis in four patients or the size of the tuberculin response in the two patients tested. No effects were discerned on eosinophil-counts or E.S.R.

LYSERGIC ACID DIETHYLAMIDE

Patient 8.—Female, aged 39. Active rheumatoid arthritis for 18 months, with inflammation mainly in hands, wrists, shoulders, and right knee. Subjective improvement in the arthritis took place during a fortnight's observation on dummy medicine. L.S.D. was given for 9 days, starting with 0.005 mg. and increasing to 0.025 mg. daily. The patient was troubled by flushing of the face during treatment. Subjective improvement continued, but there was no objective change in the joints.

Patient 9.—Male, aged 33. Rheumatoid arthritis for 4 years, and a relapse of 2 months' duration. Wrists, finger, elbow, shoulder, and knee joints were inflamed. L.S.D. was given for 11 days, starting with 0.025 mg. and increasing to 0.1 mg. daily. There were no side effects, no objective change in the arthritis, and no significant change in tuberculin reactions (table II). This patient had shown a conspicuous therapeutic response to A.C.T.H. during an episode of active arthritis a year previously.

Patient 10.—Female, aged 52, had 10 years' history of active rheumatoid arthritis with advanced structural changes in many joints. Active inflammation in the wrists and knees. L.S.D. was given for ten days, starting with 0.025 mg. and increasing to 0.1 mg. daily. No side effects and no subjective or objective changes in the arthritis were observed.

Patient 11.—Male, aged 23. Acute polyarthritis for 10 months and bronchiectasis. Acute inflammation in hands, wrists, elbows, shoulders, hips, knees, and feet. L.S.D. was given for 11 days, starting with 0.025 mg. and increasing to 0.1 mg. daily. Conspicuous dilatation of the pupils developed during treatment. There were no subjective or objective changes in the arthritis. The size of the tuberculin reaction was not significantly changed (table II).

TABLE II—CHANGES IN DIAMETERS OF TUBERCULIN REACTIONS DURING TREATMENT

Patient	Treatment	Mean lesion diameter before treatment (mm.)	Change in diameter during treatment ± standard error	*Significance*
4	Glucose 1 phosphate	11.5	+1.5 ± 0.9	0.3 < P < 0.4
6	Glucose 1 phosphate	16.7	+1.7 ± 2.5	0.5 < P < 0.6
9	Lysergic acid	9.4	+1.3 ± 1.3	0.3 < P < 0.4
11	Lysergic acid	12.7	−1.0 ± 2.3	0.6 < P < 0.7

Conclusion.—In the doses used L.S.D. did not influence the course of rheumatoid arthritis in four patients or the size of the tuberculin reaction in the two patients tested. No effect was evident on eosinophil counts or the E.S.R.

Discussion

Although cortisone and A.C.T.H. diminish both experimental tuberculin hypersensitivity and the inflammation in rheumatoid arthritis, the disease has proved to be unaltered by other factors affecting experimental hypersensitivity. The degree of ascorbic acid saturation appears to be without influence on the disease, or on its responsiveness to cortisone and A.C.T.H., and glucose-1-phosphate and L.S.D. have no discernible cortisone-like effect, even in doses proportionally greater than those which diminish experimental hypersensitivity. These studies therefore provide no evidence to support an analogy between experimental tuberculin hypersensitivity and the tissue reaction in rheumatoid arthritis. On the other hand, because of the difficulties inherent in duplicating experimental conditions in man and the guineapig, such an analogy is not refuted. In the ascorbic acid studies especially, there were the inevitable differences in the basal diets.

In patient no. 3 the trends of change in the tuberculin reactions during ascorbic acid depletion and saturation were comparable to those described in guineapigs (Long et al. 1951a). We should hesitate, however, to conclude, from this single observation, that the changes observed were not fortuitous, for we have not previously studied tuberculin reactivity so long in untreated persons. The possibility of an association between ascorbic acid saturation and tuberculin reactivity in man merits further study.

Though cortisone and A.C.T.H. diminish the tuberculin reaction in both the guineapig and man, the reaction in man appears to be uninfluenced by glucose 1-phosphate and L.S.D., which have cortisone-like effects in the guineapig. We have therefore been unable to test the possibility that substances other than cortisone and A.C.T.H., which diminish the tuberculin reaction in man, may also affect the tissue reaction in rheumatoid arthritis. The study in patient no. 3 has confirmed our earlier impression that there is ordinarily no correlation between the level of tuberculin reactivity in a given person and the activity of the arthritis.

It is possible that the means by which cortisone diminishes the tuberculin reaction are different in the guineapig and in man. Though the dose used by Long and Miles (1950) in guineapigs was, on the basis of weight, comparable to that which we found necessary to reduce the tuberculin reaction in man (Lovell et al. 1953), the resulting reduction in reactivity in the guineapig was about 4-fold, whereas in man the reduction ranged between 15-fold and 170 fold. However, the variability in species responses to the hormones, and the fact that Long and his colleagues usually confined their observations to effects attained within a few hours of single injections of hormones, make comparison in the two species difficult.

Long and his colleagues have interpreted the cortisone effect in the guineapig as reflecting a reduction in its hypersensitivity. Some support for this thesis has been provided by Leahy and Morgan (1952), who found that cortisone inhibited the cytotoxic action of tuberculin on sensitised guineapig cells in vitro. The means whereby cortisone diminishes the tuberculin reaction in man has not been identified. In the doses we used we found that the inflammation evoked by a direct irritant, manganese butyrate, was also reduced by cortisone, and a similar effect has been described on the inflammation evoked in human skin by ultraviolet light (Järvinen 1951). Possibly therefore, the action of cortisone on the tuberculin reaction in man reflects, at least in part, a non-specific diminution of an inflammatory response, rather than an interruption of the immunological mechanism which initiates a hypersensitivity reaction.

Summary

The effects of some factors which modify experimental tuberculin hypersensitivity have been studied in patients with rheumatoid arthritis.

Ascorbic acid depletion and saturation did not influence the course of rheumatoid arthritis or the therapeutic effects of cortisone and A.C.T.H.

cortex the mind is damaged, and we know that mental stress and anxiety influence the functions of the body and may in time lead to disorder of its structure. Nevertheless, in the past, and at present, a lack of clear thinking about the body-mind relationship has tended to lead to overemphasis upon one or other. On the one hand there have been many dynamic psychologists who have overstressed the psychological and disregarded the physical factors in the causation of mental disease: on the other hand an exaggerated emphasis upon the importance of the physical state of the nervous system has sometimes encouraged a nihilistic attitude to psychotherapy. At present a much more balanced attitude is in general tending to prevail. It is recognised that a depression can usually be most readily abolished by attacking its physical basis, empirically, by electrical convulsant therapy: on the other hand, even though it be conceded that ideas and feelings have their counterpart in the organisation of the nervous system, it is often impossible to change a patient's ideas and feelings, including their neurological basis, except by presenting other ideas and feelings to his conscious mind. Whatever our philosophical view, then, most of us can agree that mind has a pragmatic importance as a function of the organism.

Some people will say that this is enough: why bother with the philosophical niceties? In the long run I believe it does make a profound difference, not only to individuals, but also to the whole of a culture whether the mind is regarded as being explainable in terms of neurophysiology or not. The man who regards the mind as a function of the nervous system is necessarily analytical in his approach. He seeks to explain the whole in terms of the parts, the parts being the last resort the electrical impulses in the individual neurones, and it makes little difference whether he seeks to explain human behaviour in physiological terms or, like the psycho-analyst, in terms of conflicting psychological drives or other partial mental organisations. Over against these ideas stands the holistic view, which, whether through philosophical reasoning, act of faith, or mere empiricism, still believes that man is more than can be explained as the summation of his nervous impulses or the resultant of his conflicting complexes. This view is unfashionable in some quarters at the moment, but even by a mere pragmatic test it may yet prove a better basis for our understanding of our patients and, indeed, a better foundation for civilisation than the alternative.

Philosophy in Practice

What are the implications for medical thought and practice of a philosophy of medicine based upon the idea of the organism as a whole? Its intellectual climate would permeate the whole of medicine, for it is not a form of thought peculiar to some kind of generalist as opposed to the specialist: on the contrary, it is the essential background of specialism. The specialist needs to look at the whole man from his own particular angle, while the generalist looks at all the angles from the standpoint of the whole man. Dermatology, for example, however superficial its subject matter, has long ceased to be merely skin-deep, for it includes in its scope the whole range of life from the human mind to the filterable virus, a vast external environment, and complex metabolic transactions within the body. But the differentiation of medicine, and the development of specialties on an anatomical basis, has necessarily led first to those discoveries which could most easily be made by observation of the system concerned, while those disorders which involve complex transactions of the whole body often still elude our understanding. Hence, in the field of research a team of varied experts and close liaison between specialties is becoming increasingly necessary.

If we are not to become lost in the increasing complexity of medical science and endless multiplication of facts, we must always keep in mind the need for clarification and simplification by means of general principles. These are essential not only for the instruction of students but also for the continued education of doctors themselves. Nowadays none of us can hope to grasp in detail more than a fragment of the available knowledge: for the rest, when it comes to practice, we have to do what the experts tell us. In this situation the danger is that the inevitable modern emphasis upon techniques will end by making us all for much of the time mere technologists. We can be saved from this only if we understand the basic principles underlying the techniques, and if we can relate them to a philosophy of medicine.

In this context the general physician has, in my view, two contributions, to make which are of peculiar value and which, though distinct, are in no way mutually exclusive. In practice he has to survey the patient as a whole from the diagnostic and therapeutic points of view, while in thought it is he who is at present best equipped to develop and expound the transactional view of medicine. This, however, is a task in which joint discussions can play a most important part, whether by a diagnostic team or a joint round, a clinicopathological conference, a research group, or a medical society meeting.

The education of the medical student must be related to the functions which the general practitioner has to perform in modern medicine. This is a subject which has been, and is still being, much discussed. I wish to deal with only one aspect of it now—namely, how general practice might be animated by the philosophy of medicine which I have been discussing. It is almost a commonplace that the general practitioner is above all the doctor who sees the patient as a whole. He must be an expert in diagnosis over a far wider range than is either necessary, or possible, for any other kind of doctor. In treatment I hope it may be made practicable for him to treat not only minor ailments but a good many of the more serious conditions which do not require to be treated by highly specialised techniques. But the general practitioner above all deals with the patient as a whole man in relation to the environment in which his life is lived, his upbringing, his family life, his work, and his pastimes. He should know him through and through in mind, body, and estate, and no team of experts can ever take his place in the life of the patient.

It follows that undergraduate medical education needs to be the subject of more conscious planning than it has received, or, at any rate, acted upon: it should be designed first to educate the student in the general principles of medicine, and then to teach him their practical applications in the work which he will have to do as a general practitioner. Less than this is inadequate: more, during the undergraduate years, is a work of supererogation.

Finally, we are all, I believe, conscious of the existence of subtle threats to the status of the doctor in the modern community. The causes of these are varied and complex and I shall make no attempt to analyse them now; nor am I at the moment concerned with status as such. Status, however, is related to influence, and if the unique influence of medicine upon the community were to be diminished I believe that something of the greatest value would be lost. But is medicine really unique? That question is being asked in a spirit of scepticism in some quarters today and not only our place in the National Health Service, but the whole development of the service, depends upon how it is answered.

In what sense, then, is medicine unique? By what right do we doctors claim either special authority or the special privileges that go with it? The answer, I think, is simple. Medicine alone takes as its province the whole man. It is not concerned only with his needs α-D glucose-1-phosphate and lysergic-acid diethylamide had no effect on rheumatoid arthritis or on the tuberculin reaction in man

The possibility is discussed that the means by which cortisone diminishes the tuberculin reaction in the guineapig and in man may differ

We gratefully acknowledge the coöperation of the patients taking part in this study We are indebted to the Nuffield Foundation for their generosity in making the grant which enabled these studies to be undertaken, to Merck & Co for their gift of cortisone to the joint committee of the Nuffield Foundation and the Medical Research Council, part of which was used in these studies, and to this same committee for A C T.H , to Dr H. H Green, of the Ministry of Agriculture veterinary research laboratories, for the gift of P P D , and to Dr H M Sinclair for his advice on ascorbic acid estimations We also thank Roche Products Ltd for giving us glucose 1-phosphate, and Sandoz Products Ltd for giving us lysergic acid Finally we are indebted to Prof G W Pickering for his encouragement and to Dr D A. Long for much helpful discussion and for suggesting the trial of glucose-1-phosphate and lysergic acid

SURGEON

COUNTY HOSPITAL, YORK

THOUGH phæochromocytoma is rare it is being diagnosed more often, and will become increasingly important if it can be shown to be amenable to safe surgical removal Complete and lasting cure of an otherwise fatal disease is thus possible

The subject has been reviewed by Mac Keith (1944) and Walton (1950) in this country, Burrage and Halsted (1948) and Cahill and Aranow (1949) in America, and others

Our purpose in reporting this case is to record the successful control by benzodioxane ('Piperoxane') of the rise in blood-pressure on handling the tumour, and by *l*-noradrenaline (*l*-arterenol) of the fall of pressure after its removal

CASE-RECORD

A married woman, aged 30, was first seen at the medical outpatient clinic in April, 1951 She complained that for the previous six months she had had headaches, usually vertical and coming on towards evening She also had attacks of faintness with loss of power in the limbs and with tingling in the hands After three or four minutes the power would return to the limbs, with simultaneous flushing of the face and pulsation in the head These attacks had become increasingly frequent, occurring almost every other day The headaches had, however improved a little As the attacks became stereotyped, she noticed in addition pallor of the face, arms, and hands, palpitation, aching in the shoulders, cramping abdominal pain nausea, salivation; and sweating Between the attacks she felt perfectly well, though she had recently tended to constipation and increased nocturnal frequency of micturition. Her past history was irrelevant, but she had had infective hepatitis within the previous year and had made a good recovery. She had two children, aged $7^1/_2$ years and 18 months, pregnancy and parturition were normal on both occasions

On examination the patient appeared healthy No abnormality was found on physical examination except a palpable right kidney, the significance of which at the time was doubtful The patient had, however, hypertension (170/120 mm Hg when sitting) Subsequent examination proved that this was persistent, but the blood-pressure was labile and showed changes according to posture—e g, lying 225/125 mm Hg, standing 160/100 mm Hg The patient was admitted to hospital twice for investigation, but the described attacks were not observed. Nothing abnormal was found in the urine Intravenous and retrograde pyelography suggested a deformity of the right renal pelvis, but the changes were minimal The basal metabolic rate was + 15%

The benzodioxane test was made on two occasions by two different observers, the method used was that described by Goldenberg et al (1947) On the first occasion the test was considered positive, but on the second inconclusive

In the absence of a more clear cut diagnosis it was decided to explore the right suprarenal area, and, if no tumour were found, to do the right side of a bilateral thoracolumbar sympathectomy

Operation (Dec 3, 1951)—Premedication with 'Omnopon' gr $^1/_3$ and scopolamine gr $^1/_{150}$ was given. Anæsthesia was induced one and a half hours later with 20 ml of 5% thiopentone and 15 mg of *d* tubocurarine chloride intravenously, and an orotracheal tube was passed Anæsthesia was maintained with nitrous oxide and oxygen, respiration was assisted by manual compression of the rebreathing bag for the first seven minutes To facilitate the rapid administration of benzodioxane and noradrenaline an intravenous-drip infusion was set up

The right suprarenal area was exposed extraperitoneally through the bed of the resected eleventh rib (Fey s incision), and a tumour was found largely taking the place of the suprarenal gland The blood pressure, which had been 160/90 mm Hg before induction, rose immediately the tumour was palpated very gently, but was reduced at once by an injection of benzodioxane (piperoxane) 15 mg into the intravenous tubing close to the vein (fig 1)

Removal was started by ligaturing all vessels at a distance from the gland without manipulating it When it became necessary to lift one pole from its bed to reach the vessels on the posterior aspect, there was a second rise in blood-pressure, which was only halted by a further injection of benzodioxane 15 mg, and a third injection of 13 mg was necessary to reduce it.

The tumour was removed, leaving two small pieces of apparently normal suprarenal tissue, which had been freed from it The blood pressure began to fall at once and was allowed to do so until it reached 110/80 mm. Hg, when the intravenous bottle was exchanged for one to which had previously been added noradrenaline ('Levophed') 8 mg per litre The rate of the drip was adjusted to deliver 8 µg a minute, and this raised the systolic pressure to about 130 mm Hg without materially altering the diastolic pressure

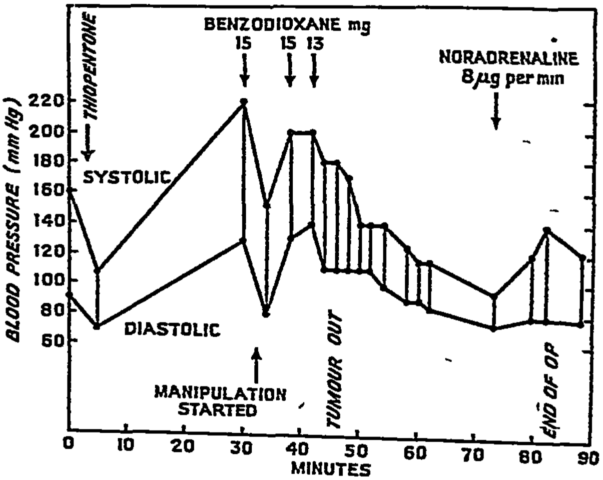

Fig 1—Blood-pressure during operation Premedication was given before administration of thiopentone.

for nursing, or with inquiries into his home circumstances or his difficulties in getting a job when he is disabled, or with this or that form of therapy, or even with him as a "through-put" item in a hospital bed in the health service. It is concerned with all these, but with how much more! With man in all the complexity of his body and mind from his conception to his last breath; and its concern extends increasingly beyond his sicknesses, to the conditions which make it possible for him to lead a healthy and a happy life.

We speak of medicine as both a science and an art, and surely these two aspects are complementary. Science is analytic, explaining, or seeking to explain, the whole in terms of the part: art is intuitive, and sees in the whole something more than can be explained as the sum of its parts. Alike in its comprehensiveness, its balance and, its insight, the medicine which we have inherited from the great masters of the past is unique; and if we remain true to its philosophy we need have no fears for its future.

SKIN DEPARTMENT, LONDON HOSPITAL

IN May, 1952, encouraging reports appeared of the value of isonicotinic acid hydrazide (isoniazid) in the treatment of pulmonary tuberculosis. It was therefore decided to observe the effects of this drug on lupus vulgaris. Oral administration was considered likely to give the best results with extensive lesions, but local injections also seemed worth a trial for selected patients with single or small lesions. Local injections into the lesions had previously been found to be most effective by one of us (Russell 1951) when using calciferol; and it is useful in a chronic disease such as lupus vulgaris to have alternative remedies and even alternative routes of giving the same remedy, thus overcoming difficulties from gastric intolerance or from the contra-indication of the oral route for some other reason. It may also be possible by local injections to reduce considerably the total dosage given. Thus, thirteen fortnightly injections of 300,000 units of calciferol amount to less than 4,000,000 units for six months' treatment, whereas oral treatment for the same length of time needs over 22,000,000 units.

TREATMENT

There were 15 patients in the survey, of whom 3 had not previously received any treatment for the lupus. 5 patients were given tablets of 'Nydrazid' orally. 6 patients were treated by local injections of 'Rimifon,' and the remaining 4 patients had both oral and local treatment.

At first the oral dosage was 150 mg. daily, but later it was found that greater improvement could be achieved by using a dosage of 300 mg. daily. Because of the rarity of side-effects we have since sometimes used doses of 400 mg. daily for adults.

For local injection a preparation containing 50 mg. of isoniazid dissolved in 2 ml. of distilled water was used. Later, owing to the difficulty of injecting even 2 ml. into small lesions at sites such as the tip of the nose, the strength was increased to 100 mg. per 2 ml. Intradermal injections were made into the whole of a lesion if it were small, or into the same portion of it if it were larger. There was also, to a varying extent, infiltration of the adjoining dermis and subjacent hypoderm. Owing to the pressure needed to give these injections, especially into the increasingly fibrotic tissues as healing progresses, an all-glass syringe was used with a medium-length intradermal needle, special care being taken to prevent separation of the needle from the syringe while giving the injection.

Injections were usually given once a week, the amount injected varying between 50 and 250 mg. in 2–5 ml. of fluid. It is appreciated that, for fair clinical trial of this method, daily injections would be preferable, but this is rarely a practicable proposition, for economic reasons, with ambulant and working patients.

Results

Fully conscious of the fact that, even after prolonged treatment by all remedies used up to the present, the most healthy-looking scar may still harbour live tubercle bacilli, and that it is only permissible to contemplate a "cure" after all signs of active disease have been absent for at least five years, we decided to make a preliminary report of the effects of treatment in 15 patients after nine months' experience of using the drug, the results being classified as follows:

(1) Clinical clearance (4+).—Freedom from all signs of activity: no redness, scaling, infiltration, or "apple-jelly" nodulation.

(2) Marked improvement (3+).—Opacity of lesions, with faint residual scaling or discoloration.

(3) Moderate improvement (2+).—Lesions more opaque and with diminished scaling and discoloration, but with slight residual infiltration.

(4) Slight improvement (1+).—Slight but perceptible diminution of redness, infiltration, scaling, and translucency.

(5) No change (0).

All observations of progress have been controlled by photography, using standardised lighting, exposure, &c., throughout.

Case-records

ORAL ONLY

Case 1.—A woman, aged 44, had suffered from phlyctenular conjunctivitis at the age of 17. At 19 she developed lupus vulgaris on the tip of the nose and on the soft palate. It was treated until she was 32, after which the scar remained sound until a year ago, when further nodules appeared on the left side of her nose. These, in spite of treatment with the Finsen-Lomholt lamp, had slowly increased in number.

Examination showed deformity of the tip of the nose and of the front of the nasal septum due to scarring from former lupus vulgaris. Several "apple-jelly" nodules were present on the mucocutaneous junction of the left naris. Radiography of the chest showed a calcified focus at the left apex, and the erythrocyte-sedimentation rate (E.S.R.) was 8 mm. in 1 hour (Westergren).

Treatment.—Oral isoniazid was given, at first 150 mg. daily for twenty weeks, then increasing to 300 mg. daily for the next twelve weeks.

Result.—After four weeks' treatment all the nodules were less prominent, and after twenty weeks minimal scaling remained. At the end of thirty-two weeks there was no clinical sign of activity, but treatment was continued. (4+.)

Case 2.—A woman, aged 52, had suffered during late childhood from spinal caries with a psoas abscess, and from a tuberculous elbow-joint; both conditions had remained inactive for many years. When she was 15 she developed "abscesses" on each side of the face, followed at 21 by red patches on both cheeks; these had gradually spread, especially during the past five years.

On examination the face was covered with confluent lupus nodulation from the level of a line drawn from the bridge of

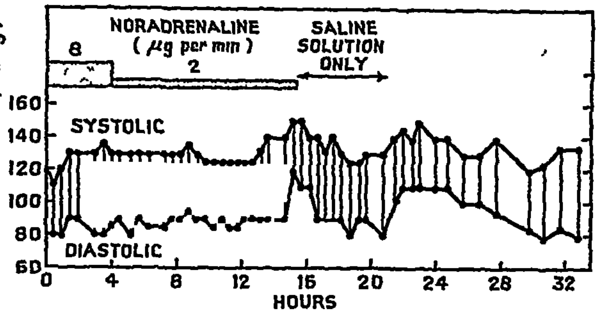

Fig 2—Postoperative blood pressure

The blood-pressure, which had been estimated as far as possible every two minutes during the operation, was recorded at five minute intervals thereafter for three hours, and subsequently at longer intervals For the first four and a half hours the same dosage of noradrenaline was continued, but, as the pressure gradually rose, the dose was reduced to 2 µg a minute, and this substance was discontinued altogether after a further eleven hours (fig 2)

Postoperatively the patient had a mild atelectasis, which rapidly resolved, and she left hospital on the twelfth post-operative day She was seen regularly until she left the district after six months At that time her blood-pressure had stayed steady at about 130/90 mm Hg since the operation and ten months after operation she reported that she remained entirely free from symptoms

Pathology—The excised tissue consisted of a rounded tumour measuring 6 × 4 × 3 cm, across which was stretched a thin layer of suprarenal tissue The microscopical appearances were typical of a chromaffin suprarenal tumour Unfortunately a biological assay was impossible

DISCUSSION

The original diagnosis was made tentatively from the history of the characteristic attacks Little support was gained from physical examination or from the doubtful results of the pharmacological test Despite admission to hospital no opportunity presented itself for a reliable observer to witness a paroxysm and therefore to detect any change in the blood-pressure Tests which depend on provoking an attack of hypertension were considered unsafe These included the histamine test of Roth and Kvale (1945), starvation, injection of adrenaline, and pressure on the supposed site of the tumour, although the latter procedure might have given valuable evidence of its presence and situation The insufflation of air round the kidneys was deemed unsafe

Both false-positive and false negative results of the benzodioxane test have been published (Dana and Calkins 1949, Goldenberg and Aranow 1950, Wilson 1950, Conley and Junkerman 1951, Soffer 1952, Tulloh 1952) Goldenberg and Aranow (1950) mention the possibility, in the case of false-negative results, that the dose of benzodioxane might be too small, and this may explain the different findings in the two tests in our case

The same considerations apply to the use of benzodioxane during operation, and the dosage (15 mg), which was calculated for our patient from the makers' table, need not necessarily be suitable for another person This dose produced an immediate fall in the initial rise of pressure, but did not protect for more than five minutes against a further rise when the tumour was handled Repetition of the same dose became necessary during the subsequent fifteen minutes before the tumour was removed, and there did not appear to be any cumulative action We were impressed by the prompt rise of pressure on minimal handling of the tumour, indicating its high degree of activity

Swan (1951) and Pantridge and Burrows (1951) used 'Dibenamine' to control excessive rise of blood-pressure, but the long action of this agent seems to render it less suitable than benzodioxane for use during operation

Bartels and Cattell (1950) attribute hypotension and collapse after removal of the tumour to left ventricular failure from excess of circulating adrenergic substances, but the satisfactory results obtained where noradrenaline has been used in the hypotensive phase strongly support the generally accepted view that hypotension results from sudden deprivation of these substances (Swan 1951, Pantridge and Burrows 1951)

Cases have been recorded (Crowther 1951) in which the hypotensive phase was treated with adrenaline infusion It seems to us that the side actions of adrenaline, which are known to vary from patient to patient, may be undesirable In particular, the rise of blood pressure from adrenaline is obtained partly at least by increase of cardiac output, and not necessarily by pure increase in the peripheral resistance Though some patients may respond satisfactorily to adrenaline, noradrenaline is theoretically the preferable agent because it probably constitutes the major part of the active material of which the patient has been deprived (Goldenberg and Aranow 1950, Crowther 1951, Pantridge and Burrows 1951, Swan 1951)

SUMMARY

Phæochromocytoma was successfully treated by surgical removal

The blood-pressure was satisfactorily controlled both during and after operation by benzodioxane and noradrenaline

These agents may reduce the risks in treating this disorder

The levophed (*l* noradrenaline) used in this case was provided by Bayer Products Ltd shortly before this drug became ordinarily available

THE ADRENERGIC AMINES OF HUMAN BLOOD

H Weil-Malherbe
M D Heidelberg, D Sc Durh
DIRECTOR OF RESEARCH

A D Bone
F I M L T
CHIEF TECHNICIAN, RESEARCH DEPARTMENT

RUNWELL HOSPITAL, WICKFORD, ESSEX

A FLUORIMETRIC method for the estimation of adrenergic amines in plasma has recently been described (Weil Malherbe and Bone 1952a), in which the amines are first isolated by adsorption on a column of alumina (Lund 1949) and then, after elution, treated with ethylene diamine (Natelson et al 1949) to form relatively stable fluorescent condensation products The method estimates the sum total of adrenaline and noradrenaline It was, however, noticed at an early stage that the condensation product formed from adrenaline differed in fluorescence from the noradrenaline derivative, the fluorescence of adrenaline being from yellow to orange and that of noradrenaline green We realised that this difference could be used as the basis of a differential the nose to the upper border of both ears, and extending downwards to the mid-neck and on to the shoulders posteriorly. Both pinnæ were involved, but the distal third of the nose, the circumoral region, and the nape of the neck were unaffected. There was no evidence of active tuberculosis elsewhere, and the E.S.R. was 44 mm. in 1 hour.

Treatment.—She was given isoniazid by mouth 150 mg. daily for six weeks, after which she was given 300 mg. daily for twenty-four weeks. She was also given general carbon-arc baths five times a week over the whole period, the face being shielded from the rays.

Result.—After two weeks' treatment the nodules were noticeably flatter, and after four weeks all the affected areas were paler and the nodules were becoming more discrete. Pigmentation had appeared, especially on the neck. By six weeks the affected area was considerably paler, the colour altering from deep reddish purple towards brown. The lesions have continued to involute slowly, in places leaving discrete brown pigmentation with atrophy, while elsewhere a reticulated pattern of erythema and pigmentation remained. At the end of thirty weeks' treatment, although there were still active nodules on the lobes of both ears and over the angles of the jaw, there was great diminution of infiltration and many areas no longer showed any activity. The E.S.R. had fallen to 18 mm. in 1 hour. (3+.)

Case 3.—A man, aged 54, gave no past history of other forms of tuberculosis. At 24 he noticed a tender spot on the upper edge of the right pinna with silvery scales, which he attributed to frostbite. The condition spread to involve the whole pinna about three years ago. While he was in hospital eighteen months ago for treatment of pneumonia, penicillin ointment was applied to his ear, causing a dermatitis medicamentosa.

Examination showed that the lupus was confined to the right pinna, there being a dusky erythema of the free border and lobe, with œdema, "apple-jelly" nodules, and scaling. There was a small fissure in the postauricular fold. Radiography of the chest showed scattered calcified healed foci: the E.S.R. was 32 mm. in 1 hour.

Treatment.—The patient was given oral isoniazid 100 mg. daily for a week, after which he noticed that the lobe was less swollen and no longer painful to touch. The dosage was increased to 300 mg. daily and this has been continued for thirteen weeks.

Result.—Six weeks after the start of treatment the œdema had subsided, the cracks had healed, and all the nodules were flatter and more discrete. After ten weeks' treatment minimal scaling remained and the ear was returning to its normal colour. (3+.)

Case 4.—A man, aged 48, had suffered from a tuberculous left knee-joint which had been ankylosed surgically. At 14 he developed lupus vulgaris, which spread and involved the right side of the nose and the chin-strap area as well as the palate and uvula. He had been treated for considerable periods with the Finsen lamp and had lived two years in a sanatorium. His recent relapse followed a period of twelve years without supervision or treatment.

On examination there was active lupus vulgaris involving the right side and tip of his nose, with nodules and scaling—the chin-strap area showed much scarring from previously treated lupus, among which were active nodules and scaling. The hard palate, soft palate, and uvula showed active tuberculosis, and there was a small cluster of "apple-jelly" nodules within the hair-line over the occiput. The E.S.R. was 6 mm. in 1 hour.

Treatment and Result.—He was given isoniazid 300 mg. daily by mouth, and after four weeks' treatment the most recent lesions, on the nose and over the occiput, were paler. After eight weeks the throat was no longer painful, but brownish nodules could be seen on the palate. Eighteen weeks after the start of treatment the nodules were much flatter and scaling was diminishing. (2+.)

Case 5.—A woman, aged 68, had tuberculous abdominal glands excised when she was 32. She has had extensive lupus vulgaris, since the age of 36, involving the greater part of her face. This has been treated with long courses of Finsen light and improved, but never with complete clearance of active lesions. She had proved intolerant of calciferol on three occasions. Radiography of the chest showed an old calcified focus at the left apex. The E.S.R. was 9 mm. in 1 hour. At the time of starting isoniazid orally she had had six weeks' rest from Finsen-Lomholt treatment. Over the face there were scattered nodules of lupus amidst extensive scar tissue resulting from past treatment. The most active lesions were on the nose, upper lip, and left supra-orbital ridge.

Treatment consisted of isoniazid 150 mg. daily for eight weeks, followed by 300 mg. daily for twenty weeks. At first she complained of indigestion, but this soon passed off. There was a history of duodenal ulceration.

Result.—After six weeks all the active areas were paler and the nodules flatter; there was general well-being, and the patient had less dread of mixing in public. When treatment had continued for twenty-eight weeks, almost all the scaling had cleared, the erythema had given place to pigmentation, and those nodules which persisted were much flatter. (1+.)

INJECTION ONLY

Case 6.—A man, aged 41, had from an early age a rash on his left elbow, which increased in size when he was 9. Owing to absence of pain or irritation no treatment was undertaken until he was 34, when lupus vulgaris was diagnosed and treated with the Kromayer lamp, with improvement until he defaulted. Three years ago he attended another hospital, where he was treated with calciferol, and some improvement followed a two-year course of treatment. Five months ago he first attended the London Hospital and was treated for a short time with the Finsen-Lomholt lamp, with some improvement.

Examination.—The active lesions covered an area 10 × 7·5 cm. just proximal to the tip of the elbow; scaling and "apply-jelly" nodulation were present amidst scar tissue. Radiography of the chest was normal, and the E.S.R. was 5 mm. in 1 hour.

Treatment consisted of weekly injections of isoniazid 50 mg. in 2 ml. of water into part of the lesion for eighteen weeks, followed by 200 mg. in 4 ml. for nine weeks.

Result.—Pallor and diminution in scaling were noted after the first three injections, and steady resolution has occurred since then, lesions near the site of injection clearing more rapidly than those at a distance. After twenty-seven weeks' treatment the skin was pale, supple, and free from scaling, with only a few remaining discrete flat nodules. (3+.)

Case 7.—A woman, aged 47, developed a localised area of lupus vulgaris below the left ear at the age of 39 and was treated elsewhere with calciferol. The condition extended locally, and she attended the London Hospital five years ago, but after only six treatments with the Finsen-Lomholt lamp she did not attend again until nine months ago, when a further attempt to give ultraviolet therapy had to be abandoned owing to a severe reaction.

Examination showed active lupus with prominent nodules, but minimal scaling over the lobe of the left ear with slight extension to the face nearby and to the scar of a former mastoidectomy operation. A radiograph of the chest was normal, and the E.S.R. was 12 mm. in 1 hour.

Treatment consisted of weekly local injections of isoniazid 50 mg. in 2 ml. of distilled water for twenty weeks, followed by 100 mg. in 2 ml. for seven weeks, the course of treatment being temporarily interrupted on three occasions owing to failure to attend.

Result.—Erythema and local swelling of the lobe of the ear diminished after two injections, and the nodules slowly decreased in size although they have not entirely disappeared. (2+.)

Case 8.—A man, aged 48, first developed lupus vulgaris on the tip of the nose when he was only 1 year old. It spread slowly, being treated with ointments and plasters. When he was 17 he first attended the London Hospital and was found to have another active lesion on the right arm; both were successfully treated with the Finsen lamp. He remained free from active lupus until he was 38, when a new lesion developed on the upper free border of the left pinna. This was successfully treated with the Finsen-Lomholt lamp. Four years ago there was a further relapse, for which he was given calciferol 100,000 units daily for nine months and intermittently ever since.

Examination showed sound scars on the left side of the nose and on the free border of the left pinna. In a wide area of scarring below the right elbow were discrete nodules and scaling. A radiograph of the chest was normal, and the E.S.R. was 9 mm. in 1 hour.

Treatment and Result.—Local injections of isoniazid 50 mg. in 2 ml. of distilled water were given weekly for twelve weeks. Treatment was then discontinued, because all the nodules had disappeared and only minimal fine scaling remained. (2+.)

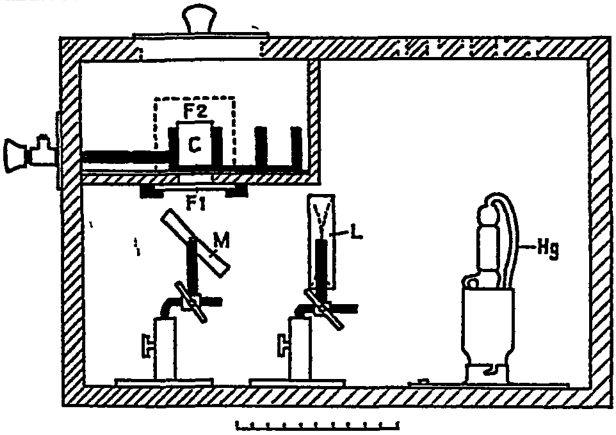

Fig 1—Fluorimeter C, silica cuvette, F_1, primary filter F_2 secondary filter, Hg 125W high pressure mercury-vapour lamp (type MBL/D, British Thomson Houston Co Ltd), L quartz lenses M, mirror

method of estimation, but the fluorimetric apparatus available at the time proved insufficiently sensitive to allow the use of the more specific, and therefore less transparent, colour filters required

It has now been possible to raise the efficiency of the fluorimeter sufficiently to overcome this difficulty Instead of the test-tubes previously used rectangular silica cuvettes (internal dimensions 23 × 23 × 10 mm) are placed closely opposite the window of the photocell box The primary radiation enters through the clear bottom of the cuvette after passing through an efficient condensing system consisting of 2 planoconvex quartz lenses (diameter 2 in, focus 5 4 in) and a first-surfaced microscope mirror (diameter 2 in) with the concave side towards the light The primary filter used (Chance OB 10) virtually isolates the 435 mµ mercury line The apparatus is illustrated in fig 1

PRINCIPLE

At our request the fluorescence spectra of the adrenaline and noradrenaline derivatives were determined by Dr W Jacobson, of Cambridge The strongest peak of fluorescence of the adrenaline derivative was found to be at about 580 mµ, whereas that of the noradrenaline derivative was at about 450 mµ. Measured with a blue green filter (Ilford Bright Spectrum Filter 623) the fluorescence intensities obtained from adrenaline and noradrenaline are almost identical, but measured with a yellow filter (Chance OY4) the adrenaline derivative has a fluorescence about four and a half times as strong as that of the noradrenaline derivative Although the results reported here were obtained with the filter combination mentioned, it may not yet be the best possible one, in fact we are still experimenting with others

Let

m = ratio of adrenaline/noradrenaline fluorescence with yellow filter
n = ratio of adrenaline/noradrenaline fluorescence with blue green filter
A = amount of adrenaline present in mixture
N = amount of noradrenaline present in mixture
y = amount of adrenaline corresponding to fluorescence measured with yellow filter
b = amount of adrenaline corresponding to fluorescence measured with blue green filter

Then the following 2 equations may be set up

$$A + N/m = y \qquad (1)$$
$$A + N/n = b \qquad (2)$$
$$\text{Hence } N = mn\,(b - y)/(m - n) \qquad (3)$$
$$\text{and } A = (y - N)/m = (b - N)/n \qquad (4)$$

EXPERIMENTAL

Procedure

The adrenergic amines are isolated from plasma and the fluorescent derivatives are prepared by the method previously described (Weil-Malherbe and Bone 1952a) Photocell currents are measured with the modified Unicam spectrophotometer Readings are taken first with the yellow filter and next with the blue-green filter Before each reading the instrument setting is adjusted by introducing into the light path in turn the reagent blank and the adrenaline standard and by setting the "transmission" dial at 0 and 100 respectively A second standard, containing 0 2 µg of noradrenaline in 10 ml, is prepared together with the adrenaline standard, and its fluorescence is determined with both secondary filters The values of m and n are determined by dividing 100 by the readings of the noradrenaline standard Under our conditions the following values were obtained (means of 17 observations with standard errors)

$$m = 4\ 44 \pm 0\ 045$$
$$n = 0\ 98 \pm 0\ 003$$
$$mn/(m - n) = 1\ 257 \pm 0\ 006$$

Analysis of Erythrocyte Extracts

After one washing in isotonic saline solution the centrifuged layer of red cells is suspended in distilled water up to the original blood volume (usually about 15 ml) The following solutions are then added (1) 5 ml of a solution containing 2% (*w/v*) sodium fluoride and 3% (*w/v*) sodium thiosulphate, and (2) 0 8 ml of 5% (*w/v*) cetrimide After standing for 30 minutes at room-temperature the stromata are spun off, and the supernatant fluid is prepared for adsorption on a column of alumina by mixing it with an equal volume of acetate buffer and adjusting the mixture to pH 8 4 (cf Weil-Malherbe and Bone 1952a)

Difficulties previously encountered with erythrocyte lysates were mainly due to incomplete hæmolysis This is avoided by the addition of cetrimide Even so, red cells must be worked up while fresh to prevent precipitation of the proteins and the clogging of the alumina columns The addition of the fluoride thiosulphate solution is designed to safeguard the adrenergic amines against oxidation during hæmolysis

Expression of Results

Whereas the results were given in terms of µg per litre of plasma in previous publications (Weil Malherbe and Bone 1952a and b, Liddell and Weil-Malherbe 1953), they are expressed here as µg per litre of whole blood The packed cell volume was determined in hæmatocrit tubes

Recoveries

Recovery experiments were made after adding adrenaline and noradrenaline in various proportions to a mixture of 10 ml of horse serum ('Wellcome Normal

Case 9.—A woman, aged 67, had not had any other form of tuberculosis. Lupus vulgaris of the tip of her nose first developed when she was 51 and cleared after general carbon-arc baths and local treatment with the Finsen-Lomholt lamp. The scar remained sound until she was 62. In the last five years both calciferol and light treatment have been used.

Examination showed nodules and scaling still present on the tip of the nose. A radiograph of the chest was normal, and the E.S.R. was 10 mm. in 1 hour.

Treatment and Result.—Local injections of isoniazid 50 mg. in 2 ml. of distilled water were given for seven weeks, followed by 100 mg. in 2 ml. for ten weeks, with rapid diminution of local swelling but with slight residual scaling and nodularity. (2+.)

Case 10.—A man, aged 31, had a nephrectomy at the age of 27 for unilateral renal tuberculosis, and he also received a three-day course of streptomycin. His bladder has since been treated by diathermy on several occasions. At the age of 4 years an indolent ulcer developed at the site of an injury to the back of the left knee. When this healed, a bright red mark remained. At the age of 25 he fell from a bicycle and injured the same knee. Lupus was diagnosed and treatment with the Kromayer lamp and calciferol caused this lesion to heal. A year ago, after the occurrence of further lupus above the right knee, he was treated with the Finsen-Lomholt lamp. This caused considerable improvement, but active nodules remained amidst scar tissue.

Treatment and Result.—After 26 weekly injections of isoniazid 100 mg. locally the nodules became considerably flatter, with disappearance of scaling and freedom from local pain on movement. After four weeks' treatment urticaria developed but was not sufficiently severe to necessitate the abandonment of injections. This was the only patient in our series to develop any undesirable side-effects. (2+.)

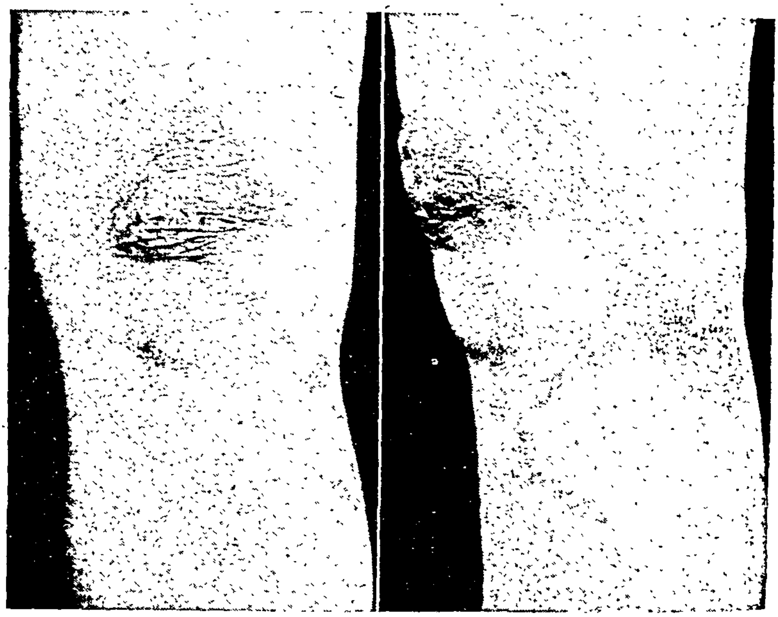

Fig. 2—Case 12 after treatment.

Case 11.—A woman, aged 51, had suffered from lupus since she was 41 and had been treated with general light-baths and the Kromayer lamp. Six years ago oral calciferol was given followed a year later by loss of weight and hæmoptysis. Radiography of the chest revealed active pulmonary tuberculosis. The chest condition has been treated with prolonged courses of *p*-aminosalicylic acid and streptomycin, both at home and in a sanatorium. The chest condition is at present quiescent. During this period the lupus received only intermittent treatment, principally with the Finsen-Lomholt lamp, with little success.

Examination showed a healed lesion over the anteromedial aspect of the right forearm, and an active lesion 6 × 4 cm. over the right elbow; hæmoglobin 88%; E.S.R. 20 mm. in 1 hour. Radiography of the chest showed mottled areas in both apices and extensive fibrosis of both upper lobes. No cavities were visible on tomography.

Treatment and Result.—Weekly injections of isoniazid were given into one portion of the lesion. For the first six weeks the dose was 50 mg. on each occasion, increased to 100 mg. for the next six injections, followed by eight injections of 250 mg. Further treatment could not be given, because she has been confined to her home with bronchitis. Although at first there was diminution of erythema and slight flattening of nodules no obvious change took place after the first six weeks. This was our only complete failure by either method of administration. (0.)

ORAL AND INJECTION

Case 12.—A woman, aged 46, gave a history of a dry scaly lesion behind the left knee since the age of 9 years. This was treated with ointments and was scraped on one occasion under general anæsthesia. The lesion remained static, but at the age of 17 an eruption appeared on the front of the left knee; this was diagnosed as lupus vulgaris and treated with ointments, without success. Two months before her first attendance at this hospital an ointment containing a sulphonamide had been applied to both active areas of lupus, producing a local dermatitis medicamentosa, which cleared when the use of the ointment was stopped.

On examination there were two erythematous lesions each about 8 cm. in diameter in the region of the right knee, with many "apply-jelly" nodules and much scaling (fig. 1). There was no active tuberculosis in other organs, and the E.S.R. was 9 mm. in 1 hour.

Treatment was begun with oral isoniazid 150 mg. daily for six weeks, increasing to 300 mg. daily for eleven weeks and then decreasing to 150 mg. for the subsequent eighteen weeks. In addition, one of the two lesions was treated with weekly injections of isoniazid 100 mg.

Result.—Both lesions have shown steady improvement, the one receiving local injections improving more rapidly. All scaling has disappeared, nodules are absent or almost flat, and pigmentation has taken the place of the former erythema (fig. 2). This case was considered to have undergone marked improvement. (3+.)

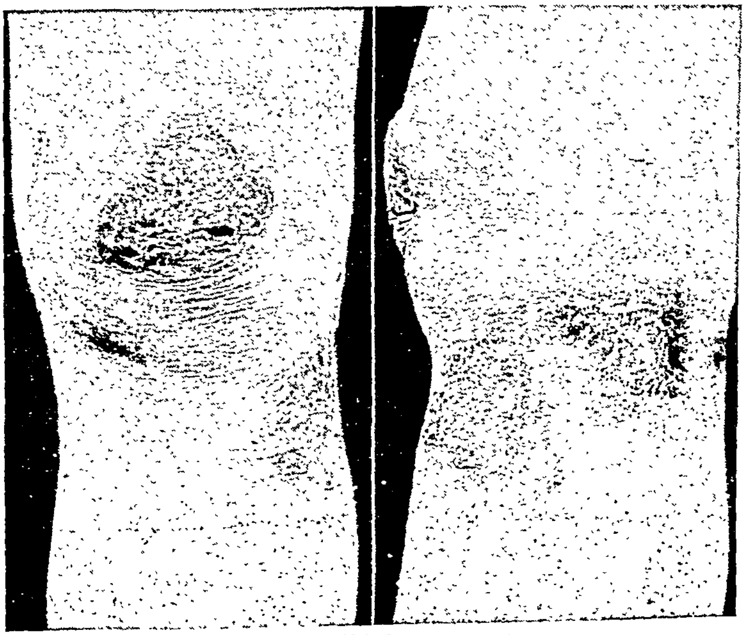

Fig. 1—Case 12 before treatment.

Horse Serum no 2 ') and 3 ml of fluoride-thiosulphate solution The amounts of adrenaline added were varied by a factor of 7 5, those of noradrenaline by a factor of 4, and their ratio by a factor of 15 In spite of this the results were accurate within ± 12%, with a standard deviation of about 6% (table I) Considering that we are dealing with unstable substances in dilutions of about 10^{-9} the result is satisfactory.

CONCENTRATION OF ADRENALINE AND NORADRENALINE IN BLOOD OF HEALTHY PEOPLE

The method has been applied to study the concentration of adrenaline and noradrenaline in the plasma and red cells of 22 male and 21 female healthy people aged 18–50 The blood was collected at about 10 A M while these people were engaged in their normal hospital duties They had not been fasting None of the females was known to be pregnant, but no inquiries were made about the phase of their menstrual cycle

The results are presented in fig 2 by plotting for each sample the concentration of adrenaline against that of noradrenaline The regression coefficient for *plasma is —1 39 ± 0 380, and that for red cells —1 32* ± 0 254 In both cases the regression is significant (P < 0 01), which means that there is an inverse correlation between the concentrations of the two amines the higher the adrenaline concentration, the lower the noradrenaline concentration is likely to be, and vice versa The regression coefficients for plasma and red cells, on the other hand, are identical within the limits of error

A striking sex difference was found in the distribution of adrenergic amines in red cells By drawing the dotted line in fig 2 the results could be separated into two groups, one of which comprises all the female samples except one, and the other all the male samples except one

Table II contains the mean values of the concentrations of adrenaline and noradrenaline and their ratio in the plasma and red cells of males and females, the statistical evaluation of the data is shown in the lower half of the table The differences between the intracellular and extracellular concentrations are highly significant for both adrenaline and noradrenaline in either sex Adrenaline concentration is highest in the red cell and noradrenaline concentration highest in plasma in men as well as in women, but the difference is less pronounced in women than in men Male plasma contains about five times as much noradrenaline as adrenaline, whereas male red cells, in contrast to female red cells, contain more adrenaline than noradrenaline Female plasmas contain significantly more adrenaline, and female red cells significantly more noradrenaline and less adrenaline, than the corresponding male blood fractions Astarabadi et al (1952) have shown that female rats are less susceptible to the lethal effect of intravenous adrenaline injections than are either male or castrated female rats

TABLE II—ADRENERGIC AMINES IN HUMAN BLOOD
(Mean values ± standard error of mean)

Subjects	Blood fraction	No of observations	Adrenaline (µg per litre)	Noradrenaline (µg per litre)	Ratio of noradrenaline to adrenaline

SPECIFICITY OF THE METHOD

It is pertinent to inquire whether the substances estimated by the method are in fact identical with adrenaline and noradrenaline, the more so as the errors of so many previous investigators have engendered a sceptical and even defeatist attitude of mind towards the problem of adrenaline estimation in blood We showed (Weil-Malherbe and Bone 1952a) that the fluorogenic substances in plasma were quantitatively destroyed by a preparation of amine oxidase at the same rate as added adrenaline To obtain further evidence some paper-chromatographic experiments were made In these, plasma samples from about 150 ml of blood were extracted with n-butanol The extracted amines were then re-extracted with 0 05 *N*-HCl, and the neutral concentrated solution was passed over a column of alumina After elution with dilute acetic acid and evaporation of the eluate the residue was transferred to paper with acid acetone and chromatographed by the method of Goldenberg et al (1949) Sections of the chromatogram were extracted with dilute HCl and the adrenergic amines estimated fluorimetrically in the extract

These experiments were done before the differential fluorimetric method was developed They are now being repeated by the new method, and the results, together with a more detailed account of the experimental procedure, will be published later Nevertheless the results so far obtained are worth mentioning at this stage

Both the extraction procedure and the chromatographic analysis involve losses, the recovery being 70–80% after either stage These losses are the same for added adrenaline as for the preformed fluorogenic material Results were calculated by applying the noradrenaline/adrenaline ratio determined by paper chromatography to the global value determined by the " direct " fluorimetric method on the same sample In five chromatographic experiments a mean concentration of 2 2 ± 0 06 µg of adrenaline and 6 8 ± 0 30 µg of noradrenaline per litre of plasma was found With a plasma volume of 60%, the figures translated into terms of µg per litre of whole blood would be 1 3 for adrenaline

Case 13.—A woman, aged 63, has had extensive lupus of the face since the age of 3. This had been treated with the Finsen and Finsen-Lomholt lamps as well as with superficial X rays. An epithelioma developed four years ago, which was successfully treated by radiotherapy.

On examination there was extensive scarring from former lupus, with a severe degree of ectropion of the right lower lid. Active nodules were present amidst the scar tissue, especially above the nose, on the cheeks, and below the chin. No evidence of active tuberculosis was found elsewhere. The E.S.R. was 11 mm. in 1 hour.

Treatment and Result.—Oral isoniazid 150 mg. was given daily for three weeks, followed by 300 mg. daily for twenty-six weeks. For the last five weeks isoniazid 200 mg. was injected twice weekly into the submental lesion, which has cleared, while all other active lesions have become considerably less scaly, with flattening of nodules. (2+.)

Case 14.—A man, aged 36, first developed lupus vulgaris behind the right knee at the age of 2. At 7 he started a three-year course of treatment with the Finsen lamp. Three years ago he reattended owing to a recurrence and was treated with the Finsen-Lomholt lamp but stopped attending six months ago owing to fractured ribs.

On examination there was a dark-red scaly area 16 × 11 cm. behind the right knee, with numerous nodules. There was no clinical evidence of tuberculosis elsewhere, and the E.S.R. was 6 mm. in 1 hour.

Treatment and Result.—For the first six weeks he was treated with weekly injections of isoniazid 50 mg. into a square measuring about a sixth of the total area affected. The injections were then increased to 100 mg. weekly for seven weeks and 250 mg. weekly for fourteen weeks. There was slow but steady improvement, especially at the site of injection, with flattening of nodules and decrease of scaling. However, after five months' treatment new nodules appeared on the medial border of the lesion. For the last four weeks oral isoniazid 300 mg. daily has been given in addition. Progress was considered to amount to moderate improvement. (2+.)

Case 15.—A man, aged 31, was born with a small white spot on the right cheek. His grandfather, father, and sister have similar lesions. At the age of 10 an attempt to remove the nævus with carbon-dioxide snow was followed by its enlargement and change of colour. The lesion has not received any further treatment and has remained unchanged in size for the past ten years. He has served in the Army for over six years, including a period in the Middle East.

Examination showed a solitary and slightly scaly lesion 3·5 × 2·5 cm. with "apple-jelly" nodules. General examination did not show any other active tuberculosis. The E.S.R. was 2 mm. in 1 hour.

Treatment was begun with oral isoniazid 300 mg. daily for nine weeks, with the addition of 200 mg. by injection twice weekly for the last three weeks.

Result.—Even after so short an interval the nodules were much flattened, with diminution in the depth of erythema. (1+.)

One further patient, a woman aged 29, had been irregular in her attendance for treatment of lupus of her nose and upper lip with the Finsen-Lomholt lamp. In consequence, the lupus had not improved, and she was given oral isoniazid 150 mg. daily for seven weeks. This caused diminution in erythema and flattening of nodules. She was given a further month's supply of 300 mg. daily but did not keep subsequent appointments and is therefore excluded from this survey.

Discussion

Isoniazid is relatively non-toxic. It can be given in doses up to 600 mg. daily without apparent ill effect. Minor subjective symptoms have been described (Brett and Braun-Falco 1953, Lucius 1952). They include nausea, palpitations, dizziness, flushing of the face, fatigue, headaches, paræsthesiæ of hands and feet, and constipation. Our patients have not complained of any of these. The only side-effect which was observed was mild urticaria in one patient treated with weekly injections, and it was by no means certain that the urticaria was caused by the isoniazid.

In addition to these minor symptoms, single reports have been made of purpura (Collins 1952, Lucius 1952), mild anæmia (Obermayer et al. 1952), sulphæmoglobinæmia (Feinmann 1952) and agranulocytosis (Varadi and Kelleher 1953).

Luntz and Smith (1953) report that the insulin requirements of diabetics receiving isoniazid may be increased; Robitzek and Selikoff (1952) reported a stimulating effect on the central nervous system, and Zabad (1953) has described psychosis developing during isoniazid therapy; but isoniazid seems to be far less toxic than calciferol, streptomycin, and *p*-aminosalicylic acid, with the reservation that time must pass before its possible delayed effects are known.

When we started this trial of isoniazid, there were no published reports of its use in skin tuberculosis, although several reports have since appeared in the Continental literature. Grütz (1952) treated 20 patients, most of whom had severe lupus vulgaris which had only shown temporary improvement on vitamin D and thiosemicarbazone. He obtained marked improvement after from six to twelve weeks' treatment, using daily oral dosages of 5–10 mg. per kg. of body-weight and considered a dose of less than 5 mg. per kg. of body-weight inadequate. Schoch (1952) found impressive improvement after seven or eight weeks' treatment in 11 out of 20 patients with lupus vulgaris and Bazin's disease, using doses of 100 mg. isoniazid thrice daily.

and 4 1 for noradrenaline The agreement with the results of the differential fluorimetric method is thus satisfactory

The important point shown by these experiments is that the fluorogenic material in plasma was concentrated in positions exactly opposite those of the adrenaline and noradrenaline spots on a reference strip (fig 3) Recent experiments in which the fluorescence was measured with different filters have further shown that the substance which has the same R_F value as noradrenaline also yields a fluorescence with the same spectral properties as noradrenaline, and similarly the substance with the R_F value of adrenaline produces a fluorescence with the spectral properties of the adrenaline derivative It has thus been established that the substances estimated in blood are identical with adrenergic amines in their affinity to amine oxidase, in R_F values, and in the fluorescence spectra of their derivatives

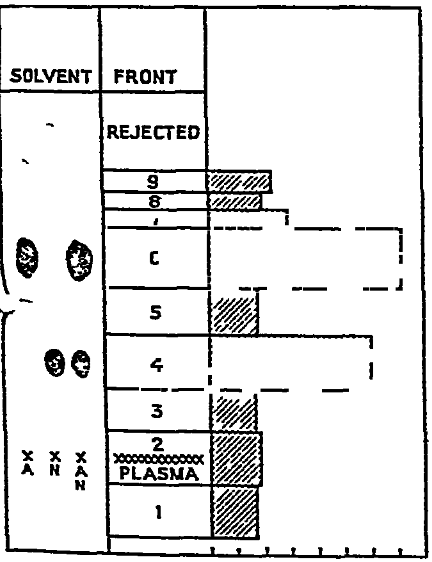

Fig 3—Paper chromatography of plasma extract on left, reference strip, after spraying with ferricyanide solution A, point of application of adrenaline solution N, point of application of noradrenaline solution , in centre, paper strip carrying plasma extract (crosses mark line of application after drying, paper was cut into sections as indicated) on right, bars indicate strength of fluorescence developed in extracts of corresponding paper section and measured with yellow filter only

SUMMARY

A differential fluorimetric method for the simultaneous estimation of adrenaline and noradrenaline in human plasma and red-cell extracts is described

Recovery experiments showed that the standard deviation from the true value is about 6–7%

The specificity of the method has been checked by paper chromatography, both methods gave similar results The two amines were identified on the chromatogram by their R_F values and by the spectral properties of their fluorescent derivatives

The mean concentration of adrenaline in plasma is 1–1 5 µg per litre of whole blood, and that of noradrenaline about 5 2 µg per litre of whole blood Red cells contain more adrenaline and less noradrenaline than plasma A significant sex difference was found in the intracellular distribution of adrenergic amines

We are greatly indebted to Dr W Jacobson, of the Strangeways Laboratory, Cambridge, who determined the fluorescence spectra of the adrenaline and noradrenaline derivatives, and to Mr J A. Mortimer, assistant engineer at Runwell Hospital who built the fluorimeter to our specifications We also wish to thank those members of the staff of Runwell Hospital who volunteered to give blood samples for this investigation.

PNEUMOFLATOR FOR TREATMENT OF RESPIRATORY PARALYSIS

R Atwood Beaver
B M Oxfd, F.F.A R C S
SENIOR ANÆSTHETIST, LONDON CHEST HOSPITAL, AND NATIONAL HOSPITAL, QUEEN SQUARE

The apparatus illustrated herewith is the prototype adaptation of a simple anæsthetic pneumoflator which has been in satisfactory use for several months It was shown at the recent conference on poliomyelitis at the Ministry of Health (Ministry of Health 1953)

Essentially this apparatus (fig 1) consists of a bellows mounted on a plain box chassis containing a motor and reducing gearbox These move the paddle of the bellows through a crank and connecting-rod The bellows have plain circular rubber valves uncovering a ring of holes and working atmospherically

At present R A F disposal motors and gearboxes, suitably adapted, are used, they are controlled by a rheostat For anæsthetic purposes the speed is regulated at about 23 r p m. The present motors have worked excellently—one for 200 hours—but there exist far superior types

The ideal, I think, is that supplied by Messrs Klaxon, 201, Holland Park Avenue London, W 11 (type HM 5CB2/WP 5, retail price £7 3*s* 6*d*) This delivers a torque at 23 r p m of 14 in lb—sufficient to produce a positive pressure in the existing machines of over 35 cm water With expansion of rubber tubing, leakage, &c, this amounts to a net inflation of over 20–25 cm, which is adequate

Owing to the nature of the motion the pressure cycle of the machine pauses at top and bottom "dead centres" Also there is a shift in the curve to the "pressure side," so that inspiration is about two-thirds the length of expiration

Further to mimic natural respiration, a later machine has been fitted with the device shown in fig 2 In this the cycle is interrupted at full inspiration and full expiration by separately adjustable stops, the rotary motion of the crank continuing unchecked by compressing the springs in the telescopic connecting-rod These springs must have a tension between the maximum thrust

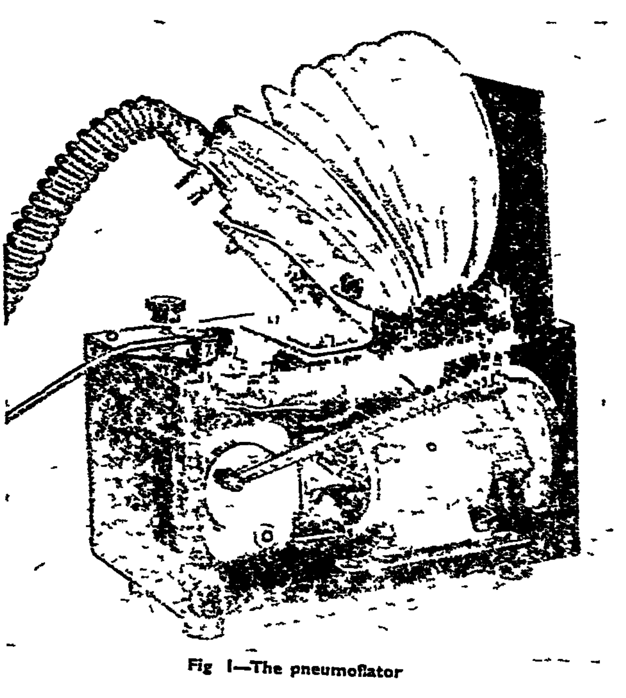

Fig 1—The pneumoflator

Since the course of untreated lupus is well known, and the number of cases suitable for treatment was limited, it was decided to dispense with controls.

Cases were distributed, so far as possible, equally between the three methods of treatment. Table I shows the results obtained by each method, and table II compares the results of those methods.

We believe that daily injections would prove as effective as, or even more effective than, the oral administration; but most patients with lupus are fully employed and daily attendances at hospital impose upon them too much financial loss to make this method practicable in most cases.

In pulmonary tuberculosis the development of isoniazid-resistant strains has been reported (Joiner et al. 1952, *Lancet* 1952). From the continuous and steady manner in which improvement has taken place in almost all our patients for up to thirty weeks we find no evidence to suggest that drug resistance has developed.

It is likely that isoniazid combined with calciferol will give better and quicker results than either drug alone, because the two drugs seem to act in different ways, isoniazid apparently having a direct action on the organisms, whereas calciferol seems to stimulate the host's powers of resistance in some undetermined way.

We consider that dosage should be at least 300 mg. a day for adults, and 400–600 mg. a day may prove to be optimal, giving maximal effect with minimal incidence of intoxication. We see no reason to estimate the dosage accurately in mg. per kg. body-weight except in children. Deviations from the average weights of adults largely depend on the amounts of fat and fluid in the tissues, for which adjustments in dosage are not needed. Nevertheless it is useful to remember that a dosage of 300 mg. daily for a woman of average build, weighing $9^1/_2$ st., provides 5 mg. per kg. body-weight, whereas a taller man of average build, weighing $12^1/_2$ st., should receive 400 mg. daily to obtain about the same dosage per kg. body-weight.

Weekly local injections are far too infrequent for a maximal response to be obtained with isoniazid, whereas in the case of calciferol weekly or fortnightly injections are effective. As with calciferol, there is a considerable increase of fibrosis after repeated injections, which makes their administration increasingly difficult.

The results obtained so far with isoniazid are impressive, but it remains as important as ever to pay attention to the patient's nutrition and environment and to try to improve them if they are defective. Calciferol still has a place in the treatment of lupus and is a valuable remedy both for systemic and for local use. General carbon-arc and mercury-vapour baths and the Finsen-Lomholt and Kromayer lamps also continue to be of value for selected patients in whom for one reason or another drug therapy is inadvisable.

Summary

15 cases of lupus vulgaris treated with isoniazid are reviewed.

Those treated orally were usually given 300 mg. daily, and those treated by injections into the lesions were given 50–250 mg. weekly. Where both methods were used the oral dosage was 300 mg. daily and the injected dose up to 400 mg. per week.

Apart from mild urticaria in 1 patient, there was no intolerance.

All the patients except 1 showed improvement, and in most of them this was progressive up to the time of writing.

We wish to thank Sister F. Hall for her great help in the study and treatment of these patients. Roche Products Ltd. supplied the solution of rimifon made up to our specific requirements, and E. R. Squibb & Sons supplied the hydrazid tablets.

LOCALISED MUSCULAR ATROPHY IN DIABETES

CEDRIC HIRSON
M.R.C.P.

LATELY MEDICAL SENIOR REGISTRAR.
WEST HERTS HOSPITAL, HEMEL HEMPSTEAD, HERTS

CHARACTERISTIC abnormalities in diabetics have bee noted in many of the body systems. In the six case reported here there were localised areas of muscula atrophy suggesting that a specific process independen of insulin atrophy was operating.

CASE-RECORDS

CASE 1.—A woman, aged 76, who had been diabetic for twelve years and controlled with insulin for four years, complained of pain, worse at night, in the arms with tingling in the feet and weakness of the arms for two years.

Examination showed areas of atrophy, which were not strictly symmetrical, in both forearms (fig. 1). The skin was normal, but muscle and subcutaneous tissue were involved in clearly defined areas extending from the lower borders of the deltoid muscles to the elbows. Fasciculation was absent, and the tendon reflexes were brisk in the arms though absent at the ankles. Cutaneous sensation was normal in the arms but impaired in the legs.

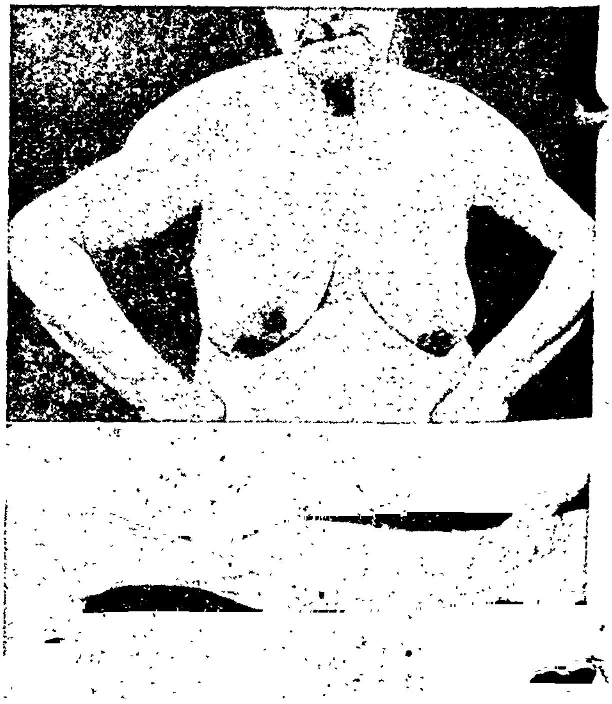

Fig. 1—Muscular atrophy of forearms (case 1).

The patient habitually injected insulin into her thighs, where the musculature was normal.

SCREWED CAP
FULCRUM
CRANK
CONNECTING ROD WITH TELESCOPIC SPRING-LOADED JOINT

Fig 2—Diagram of device for interruption of cycle

of the motor (15 lb) and the maximum thrust required to produce 25 cm water inflation pressure (8 lb)

The apparatus has been used extensively in the anæsthesia of patients for various thoracic surgical and neurosurgical operations in which paralysis was simulated with thiopentone and *d*-tubocurarine chloride so that controlled respiration was essential

Room air is supplied to the patient via the respirator, enriched with some 500 c cm oxygen per minute through a basal lead This was thought advisable, in order to eliminate excess nitrogen and ensure removal of carbon dioxide through the release valve, which is set to produce reasonable inflation No anoxæmia appeared when pure air was used, nor have there been any signs of hyperventilation at the end of 2–3 hours

No absorber has proved necessary

CONCLUSIONS

An attempt has been made to produce the simplest possible type of air-pump for continuous artificial respiration—the " mechanical student "

The cost should not exceed £20 , and, given a supply of motors, very large numbers can be produced in ordinary workshops at short notice

No compressed gas cylinders are necessary, but it is thought that a small basal oxygen enrichment is advisable

No absorber has proved necessary , the sole disadvantage is the noise of the expiratory valve

By immobilising the valves the machine can be used as an ordinary pneumoflator with absorber and basal lead , or, if thought advisable, a negative phase can be introduced into the respiratory cycle and suction as well as inflation applied

I should like to express my thanks to Messrs A Charles King for their continuing assistance, and also to Mr T Holmes Sellors, Mr Harvey Jackson, and others who have allowed me to develop these machines on their patients

Preliminary Communication

ISONIAZID-RESISTANT STRAINS OF MYCOBACTERIUM TUBERCULOSIS

The recent observations of Fisher (1952), Barnett et al (1953), and Knox (1953) have prompted us to describe our experiences with virulent strains of *Mycobacterium tuberculosis* which have acquired resistance to isoniazid

Resistant variants of H37RV and of Ravenel RV were produced in the following way Serial $1^1/_2$-fold dilutions of isoniazid were made in tubes of the Youmans modification of the Proskauer and Beck medium, enriched by 5% human serum For the first passage, the inoculum for each tube consisted of 0 02 mg (wet weight) of a lightly ground three-week-old Lowenstein-Jensen culture suspended in Youmans medium The readings obtained at 14 and 28 days are shown in the accompanying table For the second passage and again for the third passage a mixed inoculum was made from the three tubes showing growth on the 28th day in the highest concentrations of the previous passage

HIGHEST CONCENTRATIONS (µG PER ML) OF ISONIAZID SHOWING GROWTH

Strain	First passage		Second passage		Third passage	
	14 days	28 days	14 days	28 days	14 days	28 days
H37RV	0 05	10 0	0 3	66 0	66 0	66 0
Ravenel RV	0 20	33 0	33 0	66 0	50 0	66 0

Particularly in the first passage, the major factor causing the apparent development of resistance in both strains during the 28 days was the inactivation of the isoniazid It is evident from the figures, however, that genuine resistance of a high degree had been produced during the second passage and to some extent during the first The drift between the 14th and 28th days, particularly in the tubes of the first passage, is greater than that reported by other workers who used Dubos-type media (Barnett et al 1953, Knox et al 1952, Mitchison 1952, Steenken et al 1952) It is possible that the ' Tween ' in their media enhances the activity of the isoniazid—as has often been shown for many tuberculostatic substances (Fisher 1948, Zetterberg 1949, Youmans and Youmans 1948, Williston and Youmans 1949)—and to such an extent that a greater proportion of the bacilli are rendered incapable of proliferation The result of this is that eventually, when the inactivation of the isoniazid has occurred on incubation, no growth appears in concentrations which under similar circumstances permit growth in Youmans medium Thus the absence of tween from the medium employed by us would also explain why we have encountered resistance arising more rapidly and to a greater degree than has been reported for tween media

In agreement with the observations of Fisher (1952), we have found that variants highly resistant to isoniazid, obtained in vitro and in vivo, do not grow in simple media in the absence of serum Fisher's explanation of this phenomenon is that isoniazid-resistant strains of tubercle bacilli require a growth factor which is supplied by serum, bovine albumin (fraction V), or yeast extract However, it has been shown in these laboratories that strong growth may be obtained in the unmodified synthetic medium of Youmans, provided that the medium has previously been treated with activated charcoal The charcoal was maintained at red heat for 1 hour and subsequently added to the basal medium in a concentration of 1 0% After 2 days it was removed by filtration and the resultant clear medium, in 5 ml volumes, was inoculated with approximately 0 02 mg of the resistant H37RV variant described above, which had been maintained on Lowenstein Jensen slopes containing 100 µg of isoniazid per ml

The isoniazid resistant variants of H37RV and Ravenel RV, isolated and maintained in this way, now show a very much reduced pathogenicity for guineapigs This agrees with the findings of Barnett et al (1953) Isoniazid resistant strains isolated from five cases of pulmonary tuberculosis and one of urogenital tuberculosis, as well as the resistant variants of H37RV and Ravenel RV mentioned above, have produced only minimal lesions on inoculation into guineapigs The lesions were confined to the site of inoculation and to the regional lymph nodes, eated with dextran, but tubarine was used as a muscle laxant, and no hæmatomata were observed. A further eck showed a correlation between the occurrence of ematomata and the use of gallamine in cases which ad not been treated with dextran, but the incidence as not so high as when dextran and gallamine were used gether. This is considered to be due to the mechanical ffect of the maintained blood-pressure rather than to a ormation of a gallamine-dextran compound.

SUMMARY

The use of macromolecular substances in supportive herapy is described.

Since it is now possible to prepare a solution of macro-nolecular substances possessing advantages over plasma tself, the term "plasma substitute" should be discarded.

Since the primary use of these substances is for the storation or maintenance of the circulating blood volume the term "blood-volume restorer" is suggested.

The criteria for an effective blood-volume restorer are: ease of infusion, freedom from undesirable effects, reproducible composition under manufacturing conditions, elimination from the body, and maintenance of a blood level of not less than 50% of the amount infused at the end of twenty-four hours.

These criteria could only be met by the development of a new type of dextran solution.

The steps in the development of the new material are described and its clinical advantages are discussed.

The number of people involved in this investigation makes individual acknowledgment impossible. We wish to thank everybody concerned, particularly members of the department of surgery and the nurses of Manchester Royal Infirmary, and Mr. W. A. Magauran, F.R.C.S., of the Lancaster Royal Infirmary, for their assistance in the clinical investigation; Mr. L. E. Martin for the physical chemistry; Mr. F. Fowler for the large-scale production of the various types of material; and Messrs. Bengers Ltd. for unlimited supplies of 'Dextraven.' The diagrams were drawn by the department of medical illustration of Manchester Royal Infirmary.

REJECTION DYSPEPSIA

G. GLADSTONE ROBERTSON
M.D. Glasg.

THE considerable recent advances in the knowledge of body-mind relationships have sprung largely from the so-called psychosomatic approach, whereby the mental states of those suffering from various physical disorders and diseases are assessed and compared. Contributors in this field do not claim that disorders of the body are due to those found concurrently in the psyche or vice versa. They are generally psychiatrists or physicians with a psychological leaning, primarily motivated in outlook and training by a desire to improve mental health, and tend to lay emphasis on factors in the earliest years of life.

This paper is based on experience in general practice among ordinary people whose higher levels are intact, the girls who are the mothers of the future and the boys who marry them, folks who suffer from crops of boils one year and a succession of colds the next, those who get cancer of the breast and others who develop fibroids, women with dysmenorrhœa and men with peptic ulcer —in fact the whole range of the common afflictions acquired by mankind. The frequent occurrence of a sequence of different illnesses in the same person suggested that the affections were determined not in the earliest years but by variations in the later conditions of life. I do not claim originality for my method of approach or for many of my observations; but I believe that certain of my correlations are new, and that my interpretation of a common and troublesome disorder may be useful to practitioners and physicians who have not been working or thinking on the same lines.

These particular observations may be said to date from 1935, when the work of Halliday and others led me to consider emotional factors in the causation of the chronic disorders now termed psychosomatic. I began at that time to take histories from this viewpoint.

I found that many of my patients were women complaining of abdominal distension, eructations of wind and of small quantities of gastric secretion (usually termed "acidity"), nausea, and occasional vomiting. At first these symptoms would appear infrequently and pass off quickly, but later there would be acute exacerbations (often called bilious attacks), usually attributed to greasy food; and some patients rarely had a day free from belching or dyspepsia.

What struck me first was that it was very rare for *men* to have such symptoms and yet have no pain: typically the digestive troubles of the male began with pain and not nausea, whereas the female might have nausea but remain free from pain for years. I began to wonder, therefore, why only women—and they were almost always married women—were bilious in this way. I questioned them and got them to talk; but, though some of them mentioned their marital relations, these were not emphasised. Often the stomach disorder was mentioned only as a subsidiary complaint: the predominant symptoms might be those of an anxiety state, premenstrual tension, varicose veins, visceroptosis, uterine prolapse, gall-stones, hypertension, or rheumatism. I felt that there must be a definite answer; and then, as so often happens, the case turned up that provided the key to the others.

AN ILLUMINATING CASE

Case 1.—Mrs. A., aged 52, had had her first menstrual period at 16 years 3 months; she had been married 30 years but had never been pregnant.

Complaint.—Abdominal distension with noisy eructations of wind, burning abdominal pain, sensation of "stone" in the epigastrium, nausea, frequent vomiting unrelated to eating, constipation with occasional attacks of diarrhœa, frequent sore throats, palpitation and general nervousness, extreme irritability, falling sensation centred in the uterus and bladder.

Physical Examination.—Each organ system had been investigated in turn, to the limit of ordinary hospital technique, with negative result.

History.—The youngest of five siblings, she was shy and self-conscious as a child. Her relationship with her parents lacked warmth, affection, intimacy, and understanding. From her earliest recollection her mother, who was often confined to bed until she died at the age of 81, had required her help in the home. On this account her school work was poor and she became unpopular with teachers as well as classmates. The onset of headaches terminated her scholastic career at the age of 12. Sore throats commenced when she was 14, after the death of her only girl friend from diphtheria.

In 1916, at the age of 22, she married her fiancé while he had 48 hours' leave from military service. They did not live together until a year later when a varicose ulcer secured for him a month's convalescence. He joined her in Prestwick where she was spending a holiday. Within a few days of his arrival she began to feel bilious. Nausea and vomiting continued until her husband rejoined his unit. Her unfortunate indisposition was assumed to be due to sewage contamination of seawater at the bathing site. Next summer her husband, now stationed in the south of England, was released from duty owing to a recurrence of the leg ulcer. She decided to spend a few months with him, but the reappearance of nausea and vomiting soon after her arrival convinced her that the "air" did not suit her and led to a speedy retreat northwards. Once more separation from the husband was followed by instant recovery, but demobilisation ten months later brought her respite to an end

The nausea, wind, acidity, and bilious attacks which were her lot for 27 years she attributed to the irreparable damage sustained by her stomach and liver when in Prestwick in 1917 During these years she had sought relief from every source known to her, including general practitioners, hospital physicians, surgeons, and gynæcologists, osteopaths, Nature healers, homœopaths, physiotherapists, and chiropractors Surgical intervention had included fixation of floating kidney at 31, abdominal fixation of the uterus at 32, colopexy at 34, and cure of a ventral hernia at an operation scar at 35

Findings and Inferences—Her early life was characterised by lack of affection for her father with consequent inhibition of her erotic growth, retardation of menses, and inability to accept the male sex. Her association with her mother was made closer by the perpetual ill health of that parent She never experienced sexual desire or orgasm Flatulent dyspepsia, which first appeared with the commencement of marital relations, was always aggravated by coitus All her symptoms were accentuated during the premenstrual week

With the facts of this case so plain before me, I began to see the significance of the marital relations, the separations, and the divorces of so many of my previous patients As each old patient came back, and each new one arrived, it became apparent that the married woman with this syndrome either had always been frigid or had recently become so Here are some further examples

FURTHER ILLUSTRATIVE CASES

Case 2—First menstrual period at 15 years 5 months She had excellent health until her marriage at the age of 23, but then suffered from a vaginismus which rendered coital attempts difficult and painful Dysuria, nausea, flatulence, and bilious attacks followed Stretching of the vaginal introitus and dilatation and curettage of the uterus took place two years after marriage Her only pregnancy, which commenced in a few months, was associated with nausea and vomiting Within a year of the confinement colporrhaphy was performed because of bearing down pelvic discomfort Ten years later a colopexy was done Progressive increase in the severity of flatulence, acidity, nausea, and bilious attacks led to 16 radiological examinations being made between the ages of 38 and 46 On the last occasion a gall stone was discovered and the gall bladder removed In three years' time the persistence of her symptoms drove her to seek surgical aid yet again Once more it was given ungrudgingly, adhesions now being sepatated. When at the age of 53 she first consulted me her symptoms had abated but little Her meals were followed by noisy eructations of wind, very small amounts of fat provoked bilious attacks, while "chills" were blamed for her bouts of dysuria

Findings and Inferences—Like the first patient, she was sexually frigid and coitus seemed to instigate and maintain both her acute and chronic symptoms Gall stone deposit was preceded by many years of functional disorder The husband had contracted a duodenal ulcer within five years of marriage

Case 3—First menstrual period 13 years 2 months She was 69 years old at interview, having married at the age of 18 She grew up in a happy home with affection for both parents Her early relationship with her husband was exciting and satisfying, the first four pregnancies being uncomplicated by nausea and vomiting After the birth of the fourth child a proportion of coital acts took place in the absence of desire or orgasm on her part The incidence of sickness mounted in each of the succeeding pregnancies Following the seventh confinement she lost all sexual interest, but it was not until after the ninth that she began to suffer from nausea, wind, acidity, and bouts of vomiting in the intervals between pregnancies Two of her eighteen pregnancies terminated in miscarriage Dyspepsia was heightened at the menopause Her husband's death, eight years ago, was followed by slight improvement She had been an assiduous and faithful attender of outdoor hospital dispensaries, thereby increasing the running cost of these institutions over the last forty years by her consumption of roughly 1200 bottles of medicine

Findings and Inferences—In this case the maternal component of the patient's personality became dominant at the expense of the erotic, through mothering her own ever increasing family

Case 4—First menstrual period at 17 The eldest of s siblings, she was 51 years at interview, had married whe and had given birth to four children In childhood she h and feared her father, a habitual drunkard whose behav indicated dislike for his wife and children alike Dur adolescence she assisted her mother (who suffered from " weak stomach and biliousness") with housework and in t rearing of the younger children and protected her when poss from her father's abuse At marriage she professed affect for her husband, but admitted loathing for the sexual asp Within a year or two he seemed to lose interest in her a the home, eventually becoming a drunken character remin cent of her own father Her physical pattern closely appro mated her mother's—prolonged sickness in pregnancies w later a growing tendency to nausea, acidity, and bili attacks

Findings and Inferences—She illustrates the all too comm sequence of failure to acquire acceptance of the male own to hatred of the father and too strong attachment to th mother, the sequel being delayed menses, sexual frigidity, a drunken husband (his reaction to the problem), and final the likelihood of repetition in the lives of her children

Case-histories of this kind can be found at length in the books and journals (chiefly American) dealing w psychosomatic disorders, but in our standard textbook the clinical picture is discussed mainly under the heading of nervous dyspepsia, visceroptosis, and chronic chole cystitis No attempt is made to define the kind of emotion or the experiences likely to create it, and no explanation is offered for its rarity in the male

The underlying cause can, I think, be best indicated if we apply to it the term "rejection dyspepsia"

RELATION TO NAUSEA AND VOMITING OF PREGNANCY

In an earlier paper on nausea and vomiting in pregnancy (Robertson 1946) I drew attention to the ætiological significance of previous dyspepsia (cyclical biliousness in adolescent girls), mother attachment, sexual frigidity, and undesired coitus I believe it will be found that rejection dyspepsia is but a further stage in a disorganisation of function due to the same factors as pregnancy sickness The prevalence of both conditions is quite in keeping with published data on marital life and frigidity (Pearl 1938, Reich 1948) Reich gives a figure as high as 60% for the prevalence of frigidity in Germany I have failed to unearth a computation of female frigidity in this country, but of over 1000 pregnant women in industrial Glasgow whom I saw during about ten years, 12% had been completely frigid throughout their married lives, and in the others the degree and duration of sexual interest varied widely.

A SERIES OF CASES

The milder forms of rejection dyspepsia are encountered daily, and my records do not allow me to offer a representative sample, but I thought it might be of interest to analyse a series of 300 cases referred to me between 1938 and 1947 in which flatulent dyspepsia was the patient's chief complaint This series includes all patients treated by me during these years who suffered from or had suffered from "visceroptosis" or gall stones Many of the patients had endured multiple operations (e g, for uterine prolapse, rectocele, and cystocele) but none had suffered from peptic ulceration The accompanying table shows these 300 patients subdivided in respect of the factors which seem to me worthy of consideration from the ætiological standpoint

1 Mr I M Burdon and Mr J H Levack inform me that the ratio of 1 male to 57 females is in keeping with the average sex ratio of cases of gall-stones at the Victoria Infirmary and the Southern General Hospital, Glasgow

2 Of 300 patients with severe flatulent dyspepsia only 3 were single women Each of these had continued to reside with her mother for many years after reaching adulthood

3 The remaining 296 patients were married women, and they fall into three groups

and in some cases even these lesions were absent. No macroscopic disease was evident in the spleen or other organs. (The inoculum was approximately 0·5 mg. and the animals were sacrificed on the 86th day after inoculation.) In our experience, guineapigs injected with much smaller inocula of the parent strains show extensive disease in the usual organs within one month.

One of us (E. G.) is the holder of a Lasdon Foundation Research Fellowship of University College, Dublin.

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE association's spring meeting was held in Dublin on April 23–25 under the presidency of Sir REGINALD WATSON-JONES.

Transfusion of Blood, Plasma, and Plasma Substitutes

Dr. W. E. R. HACKETT (Dublin) discussed the advantages of transfusions of blood, plasma, and plasma substitutes before and during surgical operations. In anæmic patients who required transfusion before operation it was important that the blood be given several days beforehand so that the body might benefit as fully as possible. Blood given during operation had its greatest usefulness in replacing blood lost: this was often more than was realised. A common unsuspected source of blood-loss was bleeding into the tissues, and this was an important cause of oligæmic shock after injuries such as fractures and extensive limb wounds. The risks of overloading the circulation by over-transfusion were small; a commoner error was not to give enough blood. With expert laboratory help reactions from mismatching were exceptional; mistakes, when they occurred, were more often due to clerical errors or confusion of patients with similar names than to mistakes in grouping. In practice the only rhesus factor of real importance was the D antigen. So far there was no true substitute for blood. So-called blood substitutes were really plasma substitutes, and none was equal to plasma itself. A perfect plasma substitute must have the same osmotic properties as plasma; this was very difficult to achieve. The best types at present available were the polyvinyl polymers such as 'Plasmosan' and the sugar polymers such as dextran.

Ocular Torticollis

Prof. L. E. WERNER (Dublin) recalled the significance of imbalance of the ocular muscles as a cause of tilting of the head in infants and young children. When due to an ocular imbalance, such tilting could be corrected by an equalising operation on the eye muscles, though in long-standing cases there might be secondary contractures of the neck muscles. Professor Werner classified torticollis as (1) purely ocular, (2) purely cervical, or (3) combined. From the orthopædic point of view it was necessary to determine as soon as possible in every case of torticollis whether there was an ocular element in the deformity, if necessary by referring the patient to an orthoptic clinic. If an ocular defect was overlooked orthopædic treatment directed to the neck would not be completely successful.

Fracture of Head of Radius

Mr. J. C. CHERRY (Dublin) had replaced the fractured radial head by an acrylic prosthesis in selected cases in which the head was badly comminuted. Mr. C. C. JEFFERY (Exeter) believed that the operation had a definite place, especially in cases of fracture where the radial shaft was displaced upwards; such fractures were, however, exceptional. Prof. BRYAN MCFARLAND (Liverpool) had found no tendency for the radial shaft to migrate upwards, even when the radial head had been excised in children. Mr. ST. C. STRANGE (Canterbury) recalled that the position of the radius depended upon the integrity of the interosseous membrane. If this was torn by the force of the injury the radius was displaced, but if the membrane remained intact displacement was not to be feared. Mr. PHILIP WILES (London) thought that it was necessary to know the late results of prosthetic replacement before determining the place of the operation. Mr. ARTHUR CHANCE (Dublin) believed that the radius might move upwards when weight was put on the wrist (e.g., leaning on a table) even though it appeared in normal position in routine radiographs. There was an established place for the operation, but if the capitulum was found to be badly damaged at operation acrylic replacement was better avoided. Sir REGINALD WATSON-JONES (London) had no doubt that the operation was appropriate for the rare but definite cases in which fracture of the radial head was associated with rupture of the interosseous membrane and marked upward displacement of the radius.

Treatment of Club-foot

Mr. A. T. FRIPP (London) discussed the treatment of relapsed or *neglected congenital club-foot in children aged six months to ten years*. In the past four years he had given an extensive trial to the Kite technique in which wedged plasters are used, and he had been impressed by the results. The technique aimed at gradual correction without harmful force and without anæsthesia. Each of the four components of the deformity (varus, inversion, equinus, and plantaris) was corrected successively by removing appropriate wedges from the plaster and closing the gap, the adjustments being made weekly. During treatment the foot became progresively more supple, and in most cases satisfactory correction was obtained. Professor MCFARLAND agreed wholeheartedly with the principle of gradual correction without the use of force. Such a method reduced, though it did not eliminate, the necessity for operation.

Pott's Paraplegia

Mr. H. J. SEDDON (London) remarked that in paraplegia of early onset the cord might be involved by an inflammatory lesion (fluid or solid), rarely by thrombosis of the vessels, and sometimes by mechanical collapse of the spine. Paraplegia of late onset was associated either with an inflammatory process or with pronounced bony deformity. The cord changes in paraplegia were of four kinds: simple compression, infective thrombosis, pachymeningitis (rare), and longitudinal shrinkage. With conservative treatment alone paraplegia of early onset persisted in about a quarter of all cases, and paraplegia of late onset in over half the cases. Operative treatment offered a good prospect of mechanical relief: fluid pus could be drained by costotransversectomy, but solid matter interfering with the cord was best removed by anterolateral decompression (except in the neck and in certain lumbar lesions, where laminectomy offered advantages). Operation was indicated: (1) when paralysis had become complete; (2) in all cases of late onset; (3) if continued improvement was not taking place under conservative treatment; (4) when paraplegia was associated with uncontrollable spasms of the legs; and (5) if paraplegia recurred after initial recovery. In older patients operation should be considered relatively early. In cases with a visible abscess shadow costotransversectomy should be tried first, but if this was unsuccessful anterolateral decompression should be undertaken.

Mr. D. LLOYD GRIFFITHS (Manchester) described the operation of anterolateral decompression employed by Mr. Seddon, Mr. R. Roaf, and himself. He emphasised that operation was not required in every case of paraplegia. It was a difficult, formidable, and hazardous operation and patients should not be submitted to it unnecessarily. Mr. Griffiths summarised the combined results in 48 patients operated upon by Mr. Seddon, Mr. Roaf, or himself. 34 recovered enough to walk normally; 11 recovered little or not at all; and 3 died. In successful cases recovery was often dramatic. Results were better in early cases with active disease than in late cases with much bony deformity. Spinal fusion was always advisable after anterolateral decompression.

was up by 20% or more and was characteristically very variable. In over 60% of the phæochromocytoma patients, the fasting blood-sugar level exceeded 120 mg per 100 ml. on at least one occasion. Glycosuria was less common. The cold pressor test[8] was normal in 60–70% of those with a functioning chromaffinoma but in only 22% of those with essential hypertension. The finding that about half the phæochromocytoma patients had postural hypotension and tachycardia (an increase of 20 beats or more per minute) is interesting, for these signs are rare in essential hypertension. The explanation presumably lies in the incompetence of the vasoconstrictor reflexes in the presence of overriding adrenaline and noradrenaline effects. Perhaps the most helpful feature is the characteristic paroxysmal nature of the episodes of hypertension in many patients with phæochromocytoma, but neurogenic paroxysmal hypertension has been described,[9] and the adrenaline release in spontaneous hypoglycæmia may closely mimic a paroxysm due to a phæochromocytoma. In children phæochromocytomas produce sustained rather than paroxysmal hypertension,[10] and in adults who have had symptoms for a long time the hypertension also tends to be continuous.

Another aspect that may help in both the diagnosis and the prognosis of phæochromocytoma is the presence of other conditions which are known to be associated with this tumour in a significant proportion of cases. Several workers[11 12] have noted, for instance, that between 10% and 20% of patients with phæochromocytoma also have manifestations of von Recklinghausen's disease; and if patches of skin pigmentation are regarded as heralding the complete form of von Recklinghausen's neurofibromatosis,[13] then this proportion is probably higher. Glushien et al.[12] describe 3 patients with phæochromocytoma, of whom 1 also had neurofibromatosis and the other 2 angiomatosis retinæ (von Hippel), which is another neurocutaneous disease and can be mistaken for the retinopathy of malignant hypertension. These workers suggest that the association of either von Recklinghausen's disease or angiomatosis retinæ with hypertension increases the chances that the cause of the hypertension is a phæochromocytoma, and they go so far as to prophesy that a connection will later be proved with other neurocutaneous diseases, such as tuberous sclerosis and angiomatosis of the Sturge-Weber type, with its visual defects, contralateral hemiplegia, migraine, epilepsy, and commonly mental impairment. It may be worth while inquiring for a family history of these conditions in known cases of phæochromocytoma. Von Recklinghausen's disease, it should be remembered, is very versatile in its manifestations,[14] which include single or multiple nodular or plexiform subcutaneous neurofibromata, patches of skin pigmentation, asymmetry of growth, scoliosis, radiological "cysts" in bones,[15] defects in hearing associated with acoustic neuromata, and mental impairment. Moreover, in the matter of prognosis, even if a phæochromocytoma is successfully removed and the hypertension relieved, there is still a more than even chance, according to Charpentier,[16] that a patient with von Recklinghausen's disease has mental impairment, and a fair chance, according to Hosoi,[17] that the fibromata will undergo sarcomatous change. And if the pessimist is to finish his say, the increased likelihood of malignancy of the breast when there are neurofibromata in it should be mentioned.[18] In angiomatosis retinæ blindness may follow, and there is a 20–25% chance of an angioma or a cyst elsewhere in the brain,[18] although it may show itself relatively late in life.

When all the clinical effects and the possible associations of a phæochromocytoma are considered, it seems that a correct diagnosis should be possible in a high proportion of cases; but in some of them the prognosis may be poorer because of the conditions which quite often accompany it.

"PSEUDOLUETIC PNEUMONIA"

THE pneumonias are a group of diseases which we think of in many different ways. For instance, we consider lipoid pneumonia largely in terms of morbid anatomical appearances, while in staphylococcal pneumonia we include the bacterial cause of the histological changes and in aspiration pneumonia the mechanical cause. Other subdivisions rest only on clinical, anatomical, or even serological criteria. Thus, in 1936 Fanconi called an illness he had observed in children "pseudoluetic perihilar bronchopneumonia";[19] A similar condition has been named "Wassermann-positive lung infiltrations" by Hegglin,[20] and more recently "pseudoluetic virus pneumonia" by Herzog and Pulver,[21] who describe 37 examples of the "disease," diagnosed between 1940 and 1952. The common features were a short benign illness with respiratory symptoms, radiographic abnormalities in the lung fields, and a transiently positive Wassermann reaction. The bacterial population of the sputum is not recorded. Serological tests for virus infections were not carried out, and cold agglutinins were not demonstrated. There is, therefore, no acceptable evidence that the illnesses were due to a virus. The clinical and radiographic features alone do not distinguish these cases as a special group of the pneumonias. The only unusual feature is the positive W.R.; but, as Herzog and Pulver point out, a positive W.R. may occasionally be found in many other febrile conditions. The only infections that produce a relatively high proportion of positive W.R.s are syphilis, yaws, leprosy, and, to a less extent, malaria.[22] None are likely to have been the cause of these pneumonias; and it is highly improbable that a positive reaction would lead to a diagnosis of the cause of a pneumonia. The object in classifying the pneumonias should be to discover their causes; and a new clinical subdivision is only valuable if it promises to give such help. For this reason, "pseudoluetic pneumonia" seems a misleading title.

THE LANCET, 7, Adam Street, Adelphi, London, W.C.2

Mr. F. W. Holdsworth (Sheffield) said that with the introduction of anterolateral decompression our ideas on the treatment of Pott's paraplegia had been revolutionised. Operation seemed strongly indicated in any case where recovery was not occurring with conservative treatment. Antibiotics had helped to make operation safer. Mr. Norman Capener (Exeter) suggested that operation should not be undertaken lightly. The operation he described was essentially the same as that recommended by Mr. Griffiths, but he thought it unnecessary to remove more than one or two ribs. Mr. J. Dobson (Wrightington) thought that anterolateral decompression should be done only in specially equipped centres. He emphasised the importance of treating the tuberculous patient as a whole by constitutional measures. Mr. R. W. Butler (Cambridge) believed that anterolateral decompression would greatly shorten the duration of paraplegia and would permit recovery in many patients who would not otherwise recover.

Treatment of Early Poliomyelitis

Sir Harry Platt (Manchester) remarked that a generation ago outbreaks of poliomyelitis were always small and children were almost exclusively affected. The main problem was to prevent and relieve crippling deformity. As a result of the greatly increased incidence of poliomyelitis and the frequent affection of adults, the subject had become even more important. The prevention of deformity was still one of the main problems. This could be tackled efficiently by the orthopædic surgeon only if the patient came under his care at an early stage. There was unfortunately a tendency for patients to be brought too late to the orthopædic surgeon.

Mr. D. M. Brooks (London) outlined a programme of treatment for patients with poliomyelitis. He recalled that the aims of treatment were to save life, to prevent deformity, to restore function, and to rehabilitate the patient. The orthopædic surgeon should have access to the patient at an early stage, and he should have a full knowledge of the complications that endangered life and of their management, including the use of different types of respirator. In preventing deformity the surgeon must remember its two causes—faulty posture and muscle imbalance. Faulty posture, which might be assumed in an attempt to minimise pain, was always preventable by appropriate splints. Muscle imbalance was more difficult to counteract, especially in children; when this was great, it was impossible to prevent deformity simply by external retentive apparatus. Relatively early tendon transplantation was often necessary. Active use of recovering muscles should be encouraged with relative caution; fatigue might be harmful during the early months. Electrical muscle tests were of value in determining at an early stage whether paralysis was going to be permanent. In general, if a muscle showed no sign of recovery within three months it was unlikely ever to recover. This knowledge enabled an early decision to be made on the question of tendon transplantation. Mr. H. H. Langston (Winchester) said that it was important that the orthopædic surgeon should have early access to patients with poliomyelitis. There was a tendency for too much delay. Professor McFarland believed that early orthopædic management would best be secured by the efforts of individual orthopædic surgeons in their own areas. Mr. R. I. Stirling (Edinburgh) suggested that in time of epidemics blocks of beds in fever hospitals should be put at the disposal of the orthopædic surgeons, who otherwise might be unable to accommodate the large numbers of cases in their own wards. Mr. J. C. Scott (Oxford) believed that in the early stages the ideal arrangement was close coöperation between orthopædic surgeons, pædiatricians, and infectious-disease physicians. Orthopædic surgeons should strive to contribute more to the solution of problems of the early phases of the disease.

Dupuytren's Contracture

Mr. J. I. P. James (London) recognised contracture of the fifth finger as a distinct clinical type in which the distal interphalangeal joint was not uncommonly flexed. He had found "knuckle pads" associated with Dupuytren's contracture in nearly a quarter of all his cases; the microscopic appearance of the pads was similar to that of the palmar fascia. Plantar involvement was also common. In the elderly subcutaneous tenotomy was occasionally justified, but for the ordinary case excision of the palmar fascia through a skin-crease palmar incision and through midlateral digital incisions was recommended. The greatest hazard was œdema of the hand. Of 84 cases reviewed the result was perfect or good in 64, and fair or poor in 20. Metacarpophalangeal contractures could usually be overcome, whereas interphalangeal contractures were very liable to persist.

Amputation of all Toes

Mr. K. I. Nissen (London) said that there was a place for amputation of all the toes in cases of gross deformity with rigid, functionless, but painful toes. Such a condition most commonly followed "burnt-out" rheumatoid arthritis; occasionally it was induced by peroneal muscular atrophy or by frostbite. The nature of the proposed operation should always be clearly impressed on the patient, whose written permission should be secured. After operation it was often possible for ordinary shoes to be worn, but special shoes might be required.

Tendon Transplants for Claw-toes

Mr. R. G. Taylor (Oxford) had studied the results, in 68 patients, of Girdlestone's operation of transplantation of the long toe-flexors into the extensor expansion for claw-toes. The results were almost uniformly good.

Colles Fracture

Mr. W. Doolin (Dublin) sketched the background against which Abraham Colles occupied with distinction the chair of surgery in Dublin. Colles was a man of exceptional modesty, admired by his colleagues and by students alike for his upright character and intense honesty.

Mr. G. N. Golden (Guildford) had studied the late results in 110 cases of Colles fracture treated one to twenty years before. Most fractures had been treated by junior residents, and the usual method had been manipulative reduction and immobilisation in plaster for four weeks. 15 fractures had required remanipulation for secondary displacement. Results were assessed on the basis of pain, functional disability, and deformity. Mr. Golden concluded that age alone was not an important factor in the result. The type of fracture was of some significance, the frequency of poor results being greater after comminuted fractures and especially after fractures complicated by radio-ulnar subluxation. There was a definite and striking relationship between the quality of the reduction maintained and the result. More stable reduction, and consequently improved results, might follow the use of above-elbow plasters. Dr. W. R. Harris (Toronto) said that one of the difficulties was to maintain reduction. He and his colleagues in Toronto believed that the use of plaster-of-paris was an inefficient method, especially in comminuted fractures. In selected patients a trial had been given to mechanical fixation by pin units of the Roger Anderson type. In 23 cases observed for from two months to five years after treatment there had been no recurrence of deformity and no patient had lost more than 5° of wrist movement. In 2 cases the pin fixation had to be abandaoned because of pin-track infection.

Median-nerve Compression in the Carpal Tunnel

Mr. J. S. R. Golding (London) recalled that pain and tingling in the distribution of the median nerve in the hand were commonly due to compression of the median nerve behind the transverse carpal ligament. He had studied the clinical features and results in 50 patients subjected to operation. Most patients were women in middle life, and in half the symptoms were bilateral. Tingling at night was prominent, and was often relieved by hanging the arm out of bed or shaking it. There was usually impairment of sensation, and sometimes there were motor weakness and wasting, which might be confined to the abductor pollicis brevis and opponens pollicis. The causes of the narrowing of the tunnel fell into two groups—non-traumatic and traumatic. Non-traumatic conditions included ganglion, tenosynovitis, changes in the transverse ligament itself (acromegaly, Leri's pleonosteosis), and idiopathic. The traumatic group included early lesions such as hæmatoma, carpal dislocation, and fractures with displaced fragments, and late lesions such as old fractured scaphoid and gross traumatic arthritis. The results of decompression by division of the transverse carpal ligament were good. The symptoms were almost always relieved. There was usually good or moderate recovery of sensibility, but motor impairment often persisted.

Edward Hallaran Bennett

Mr. W. Gissane (Birmingham) paid a tribute to the memory of Edward Hallaran Bennott (1837–1907), a former

HOSPITAL COSTING
ITS IMPORTANCE TO THE DOCTOR

A F MOHUN
M D Lond
PATHOLOGIST, ARCHWAY GROUP LABORATORY, WHITTINGTON HOSPITAL, LONDON

IT is probable that in the next year or two hospitals will adopt some form of departmental cost accounting in their official periodic statements of their financial position Three reports[1–3] have lately discussed ways of enhancing the value of this official information This is not a narrow affair of technical accounting procedure, on the contrary, the measures finally adopted on a national scale will affect all who work in the National Health Service, whether they be whole-time salaried personnel or part-time employees It is important therefore that doctors should know what is involved and that they should not think that "this is all too complicated" We shall get the administration we deserve, a little clarification now may help to avoid a good deal of mystery later

What is Costing ?

Historically, the origin of costing systems is to be found in the steady growth of complexity in the structure of industrial concerns The financial affairs of the private citizen and the one-man business can usually be comprehended by that citizen or that business man, so that a stocktaking and an estimate of how he stands can be made at any time without great difficulty He can analyse his expenditure and income so that he knows how he is spending his money—so much on rent, rates, electricity, gas, water, and so forth But when the business is large enough to have several departments, or is making an article which is complex enough to consist of many components and accessories, then new problems arise Is department A making a big profit, and department B a loss, so that the profit on the whole business is really concealing a loss on part of it ? Or is a component part costing more to make than it would cost to buy it ready-made by somebody else ?

Clearly, the answers to these questions demand that we analyse the costs of running the business so that we can separate the items of cost belonging to department A from those belonging to department B, or the items belonging to the job of making a component must be extracted from the records of expenditure of the business as a whole Consider, for a moment, this process of analysis in relation to departments A and B Some costs will be apportioned without difficulty the wages of employees wholly employed in department A, the materials used in department A, these items are easily extracted Together with other items (if any) directly and unequivocally *attributable to the department*, these constitute the so-called "prime cost" of department A. But the department also occupies part of the whole business premises, uses the services of the managers, directors, clerical staff, shares in the benefits accruing from advertising paid for by the business as a whole, and uses electricity and other power (maybe from a central power plant) All these items, whose precise apportionment between departments is not obvious, constitute a total mass of expenditure which has been called "oncost," or "overhead" expenditure The total cost of department A therefore consists of its "prime cost" plus its due share of the "oncost" or "overhead"

In industry, the aim of the analysis of costs is to determine the cost of producing X articles, so that a proper selling price can be established, or, given a pre-existing market price for an article, to establish how many articles must be sold at this price so that the excess of sales income over the prime cost of manufacture will cover the overhead costs and leave a given margin of profit

The Hospital's Problems

In hospitals, the output does not consist of homogeneous, tangible, countable units, but rather in a complex service which is partly measurable in quantitative terms (numbers of beds, patients, X-ray examinations) and partly assessable (but with great imprecision) in qualitative terms (professional skill, general efficiency, the human touch, kindliness)

In some respects hospitals have problems very like those in industry—e g, would it be more efficient to have the laundry done by an outside contractor rather than to run one's own laundry ? Are the circumstances of a particular hospital such that some departments (building and engineering, bakery) cost far more than they should in relation to general experience ? If so, is this unavoidable, or can it be rectified ? In any case, why is it so ?

The great defect of the present system of preparing accounts in hospitals is that it does not readily lend itself to an analysis which would answer questions of this kind In the days when many hospitals were autonomous units, there was no pressing need for comparison of detailed costs as between one hospital and another Each ran itself in the way which seemed best to those in charge, but the advent of public ownership and the necessity for Treasury control has compelled thought about the most intelligent way of allocating funds, and this implies the establishment of some yardsticks to measure the needs of different hospitals and to establish priorities within a limited budget

For the medical profession, the reasonableness of these yardsticks and the implications of their use are the most important aspects of hospital costing For the finance officers in each hospital, the labour involved in making the analysis of expenditure, and the degree of detail required are also important

Costing then, is basically an analysis of expenditure in relation to results—whether those results be a service, or the production of goods No form of analysis is entirely successful, some forms are more suited to certain types of production than to others One of the chief difficulties is how to apportion expenses which do not fall with precise divisibility on several departments of activity

Solutions of these problems of apportionment and suggestions for the detailed procedures of the routine recording of income and expenditure, so that departmental costs can be ascertained with the minimum of labour, are the basis of all published work on costing If this be remembered, no one need be mystified by the activities of the cost accountant It is not necessary to be familiar with double entry bookkeeping and accounting to appraise and criticise a method of classification of expenditure (or income) in relation to the purpose of that classification The criterion is simply—does the method of classifying (analysing) the figures bring out the maximum of meaning, with the least effort on the part of the reader ?

Subjective and Objective Analyses

The existing method of analysing expenditure into headings such as Salaries and Wages, Drugs and Dressings, has been described as a "subjective" analysis It has now been proposed[2] that this analysis by subject should be made *after* the items have been classified according to departmental headings—e g, Medical Inpatients, Medical Outpatients, X-ray Department

professor of surgery in Dublin who described the injury now widely known as Bennett's fracture. Mr. Gissane said that the injury was now believed to be an adduction injury, and added that, although it might be reduced clinically without difficulty (as had been claimed by Bennett before the days of X rays), it was essential to maintain reduction under close radiographic control. Operative suture of the ruptured joint capsule might be required to prevent redisplacement; and, when necessary, this should be done early while the damaged tissues were still recognisable and easily handled. For late disability after inadequate reduction arthrodesis was preferable to arthroplasty.

AMERICAN ASSOCIATION FOR CANCER RESEARCH

THE forty-fourth annual meeting of the association was held in Chicago from April 9 to 11.

Tobacco Carcinogens

E. L. **WYNDER**, E. A. **GRAHAM**, and A. B. **CRONINGER** (St. Louis and New York) reported studies on the carcinogenicity of tobacco tars. Smoke from cigarettes, smoked in a manner simulating human smoking habits, was condensed in flasks immersed in dry ice and ethyl alcohol, and the resulting tars dissolved in acetone. One out of every two mice painted with this solution developed a papilloma, the earliest tumour appearing after 8 months; the average time required was 13 months. A carcinoma developed in one out of every six mice, the earliest after 10 months, and the average time of induction was 15 months. Some of these carcinomas metastasised to the lungs, and some were successfully transplanted for several generations. No tumours developed in the control mice painted with acetone alone.

Cancer of the Cervix

C. C. **ERICKSON** and his associates (Memphis, Tennessee) gave a preliminary report of the results of cancer screening of the general population: 20,000 women were examined by the vaginal-smear technique, and suspicious and positive smears were found in about 1·8% of women examined. Subsequent biopsies showed that about half of these women had intra-epithelial carcinoma of the cervix or invasive cancer.

S. C. **KASDON** and W. H. **FISHMAN** (Boston) reported work done since 1951 on the β-glucoronidase activity of the vaginal fluid of 386 cancer-free *pre*menopausal women: 88·6% had values below 400 units per g. Of the remaining 11·4%, the majority had gynæcological disorders such as preclinical cancer of the cervix, gonococcal and other infections, and ovarian dysfunction. Only 3 out of 16 premenopausal women with untreated primary invasive epidermoid cancer of the cervix showed vaginal-fluid β-glucoronidase activity below 400 units per g. But high vaginal-fluid β-glucoronidase levels were often found in *post*menopausal women and in those with deficient ovarian function who showed no clinical or other evidence of cancer.

Hydatid Mole

ROY **HERTZ** (Bethesda, Maryland) reported the absence of histidinuria of pregnancy in patients with hydatid mole, although high urinary gonadotrophin titres were found. As cortisone and A.C.T.H., but not progesterone, have been said to produce definite histidinuria, its absence in cases of hydatid mole may reflect a change in adrenal function. This deviation from the normal urinary findings in pregnancy may be a useful test for hydatid mole.

Cancer of the Prostate

W. H. **FISHMAN**, F. **LERNER**, and F. **HOMBURGER** (Boston) reported a method for estimating serum-acid-phosphatase of prostatic origin, which depended on the ability of *l*-tartrate to inhibit prostatic-gland acid-phosphatase.[1] This "prostatic" acid-phosphatase constituted 10–30% of the total serum-acid-phosphatase. In cases of disseminated prostatic cancer abnormal serum levels of this fraction were commoner than abnormal conventional acid-phosphatase levels. Some men, with normal conventional serum-acid-phosphatase and abnormal "prostatic" serum-acid-phosphatase were subsequently found to have cancer of the prostate, though there was no radiological evidence of bone metastases at the time of the phosphatase estimations.

Leukæmia

A. J. **ANLYAN** (New York) had studied the β-glucoronidase activity of the leucocytes of 46 leukæmic children under 13 years of age. The leukæmia was predominantly a "stem-cell leukæmia." The patients were divided arbitrarily into three groups: those with leucocyte enzyme activity below 2000 units per g. of buffy coat; those with between 2000 and 4000 units; and those with over 4000 units. The patients were equally divided among the three groups. It was found that the first group responded well to treatment, though the remissions were short and could seldom be achieved twice. The second group included many of the patients that survived a year or more and who had longer remissions than the other groups. The third group pursued a rapidly fatal course despite treatment.

Metastatic Tumours of Bone

JUDITH **BELLIN**, AGNES **HAUSINGER**, and HERTA **SPENCER** (New York) described experiments on the metabolism and removal of radiocalcium (Ca^{45}) in patients with osteolytic or osteoblastic metastases. Tracer doses were injected intravenously. The loss of Ca^{45} through the alimentary tract was similar in both groups, but the urinary excretion was 60–80 times greater in patients with osteolytic metastases than in those with osteoblastic metastases.

Tumour Growth

O. H. **PEARSON** and C. D. **WEST** (New York) discussed objective methods for the measurement of tumour growth in man. Lymphoid tumours and the myeloid tissue of acute leukæmia contained three times as much phosphorus per unit of nitrogen as muscle tissue, and thus growth or destruction of such tumours should be accompanied by a positive or negative balance of these elements in the same ratio as they exist in the tumour tissue. Slight changes in tumour mass of approximately 30 g. wet weight of tissue per day were detected in this way. Further, osteolytic tumours grew by destroying normal bone; it was assumed that growth of 1 g. of tumour caused destruction of 1 g. of bone, and hence a negative calcium balance of approximately 150 mg.; this amount of calcium loss per day was readily measured.

Chemotherapy

A new substance, 6-mercaptopurine, has recently been intensively studied at the Sloan-Kettering Institute for Cancer Research, New York. Some preliminary experimental and clinical results were presented by workers at the institute. D. A. **CLARKE** and his associates reported that this substance was a unique inhibitor of the transplantable mouse tumour, sarcoma 180. It was effective orally or parenterally. At first there was only moderate inhibition of tumour growth, but later most tumours became non-viable—i.e., unable to "take" when transplanted to normal mice. Survival-time was increased in treated mice and there was complete regression of the tumour in a significant number. J. H. **BURCHENAL** and his group gave details of some preliminary trials in over 100 patients with advanced neoplastic disease. The usual oral dose was 2·5 mg. per kg. body-weight until a therapeutic effect or a fall in the total leucocyte-count appeared. Children tolerated this dosage level for a longer period than adults. Particular caution was needed in patients with impaired renal function or very high leucocyte-counts, for difficulties in uric-acid excretion occurred when tissue-breakdown was too rapid. The main toxic sign was depression of the blood-count, but marrow examination showed none of the morphological changes characteristic of intoxication with folic-acid antagonists. 14 out of 45 children with acute leukæmia were temporarily improved, and 11 showed substantial improvement.

A. **GELLHORN** and his colleagues (New York) described laboratory and clinical studies of 1 : 4-dimethanesulphonyloxybutane ('Myleran'). This was a potent carcinostatic agent for the mouse mammary tumours 755 and E 0771, and for the Brown-Pearce carcinoma in rabbits. Clinically, they had confirmed recent observations[2,3] that the drug was useful in the management of chronic myeloid leukæmia.

S. **FARBER** and his colleagues (Boston) discussed the antimetabolite, antimalarial, and anti-cancer activity of a series of new dihydrotriazines. The monochlor and the dichlor compounds showed a definite but temporary effect in children with acute leukæmia resistant to folic-acid antagonists,

[3] Galton, D. A. G. *Ibid*, p. 208.

Laboratories. This method is described as "objective" analysis, and the terms subjective and objective are used in contrast to each other, as if they were fundamentally different modes of approach. But the proposed method of classification is really an extension of the old subjective analysis, emphasising the purpose of the expenditure by subdividing it first into departmental heads. If objective analysis stopped short at the headings (X-ray Department, Medical Inpatients, &c.) without detailing, under these headings, the subjective items (Salaries and Wages, Materials, &c.) it would obviously be uninformative. Merely to be told that the laboratories have cost £*x* per annum is of little value unless we know something about how the £*x* was spent. I conclude that the word objective is used to mean functional; it is, I think, unfortunate that the descriptions of the old and new methods of analysis should employ the words subjective and objective respectively, for the time-honoured usage of these terms, as opposites in meaning, is different from their recent use in the context of hospital costing.

The accompanying table illustrates how the terms are used. The grand total in the bottom left corner is the whole expenditure of a given hospital for a given period; it is made up of the items listed vertically in the two left hand columns. If these items are apportioned between departments, as shown in the remaining columns then the total of each of these latter columns will give the whole expenditure on each department. It is clear that this diagram analyses expenditure under two different schemes—one, by subject, the other, by department. But it is also clear that the totals of columns A, B, C, D would not be worth knowing unless each were also divided by subjects. In other words, to obtain useful information both the subjective and objective directions of analysis are required. In practice, some items of expenditure are automatically separated as subjective headings by the very process of recording the expenditure—e.g., the salaries and wages paid by a management committee involving special withdrawals from a bank on that account—and these will then need to be apportioned between departments to give the complete analysis. Other items may obviously belong to a particular department—e.g., parts for a flame photometer for the biochemical section of a pathological laboratory—but the precise subjective heading (within that department's orbit) may not be immediately obvious—e.g., the items may be a new addition to equipment, or merely the repair of an existing instrument.

These illustrations show that setting-up a departmental costing system is not simply the substitution of so-called objective analysis in place of so-called subjective analysis; it is the extension of analysis so that the final subdivisions are subjective within objective (items 1, 2, 3, &c., within Department A in the table). It is a matter of practical convenience whether one begins by dividing any particular body of expense by headings 1, 2, 3, &c., or by headings A, B, C, &c.; in the end one has to arrive at A(1), A(2), and so on, down to D(6).

So-called subjective headings	So-called subjective totals in £	So-called objective headings			
		Dept A £	Dept B £	Dept C £	Dept. D £
Salaries and wages		(1)			
Provisions		(2)			
Staff uniforms &c		(3)			
Drugs and dressings		(4)			
Fuel light and power		(5)			
Maintenance of buildings &c		(6)			
Grand total	£	£	£	£	£

The number of headings has been restricted to six 'subjective' and four 'objective' but in practice the number would be greater than this.

How detailed the analysis should be must, in practice depend upon its value relative to the labour involved in making it. This brings us to the question of the function of costing.

Function of Costing

In the health service, costing analysis can serve several overlapping purposes. These can be discussed properly only in relation to the level of administration at which the figures are to be used. One can regard the service as comprising a series of levels of administration from the Treasury (or the Minister of Health), through the regional hospital boards, the hospital management committees (boards of governors of teaching hospitals) down to the main departments of individual hospitals, and finally to such individuals as ward sisters, heads of departments, &c.

At Ministerial level the total cost of the service is crucial; but comparative costs in different geographical areas, types of hospital, sizes of hospital groupings, are possible useful results of costing analyses. At regional hospital board level, the comparative costs are useful as also are more detailed figures of comparison within their own area. At hospital management committee level, the detailed departmental costs of a particular hospital are relevant, together with comparisons with regional and national averages. In wards or departments, the figures for expenditure controllable by the sister or departmental chief are useful.

Obviously no single statement can serve all these purposes. Any attempt to make such a statement would result in huge volumes of figures whose meaning would be obscure and whose value would be merely historical, for it would take so long to prepare such a statement that the whole thing would be months (or years) out of date before it was published.

The problem, then, is to establish criteria, appropriate to each level of administration from Minister to ward staff, to determine what information is displayed, and in how much detail. There is a perennial human tendency to present figures in a wealth of detail, for apparently their completeness enhances the æsthetic satisfaction with which the compilers contemplate the final results, a satisfaction which is absent from the minds of those whose acquaintance with the detailed material is measured in hours (or minutes) rather than months. Thus the administrators who have to act intelligently on the basis of the figures, are all too often simply bemused by the complications of the tabulated statements in front of them.

Such statements are costly to prepare, uninformative or even misinformative and a hindrance to good management. The proper way to present figures is to devise the simplest possible summary of the data essential to the purposes in hand, and to present this with supplementary analyses for special purposes, or, better still, to arrange that supplementary analyses are available—in the hands of their compilers, who should be present in person—to extract the nub of a matter on the spot.

If we apply this principle to the problem of costing in the hospital service, and if we start at the level of the ward staff in a hospital, we obtain a scheme roughly as follows.

Ward Staff

These people can exercise control over wastage of drugs and dressings, breakages of glassware and china, and economy in general housekeeping in the ward. A short summary of these items of expenditure in cash and quantity is all that is needed by the ward staff. Estimated proportions of overhead costs and suchlike are quite irrelevant, and indeed may militate against coöperation in household economy by looming large in a complete costing statement—dwarfing the items over

A.C.T.H., or cortisone. They also described further work on the effect of triethylenephosphoramide (T.E.P.A.) on malignant melanoma. Regression of malignant melanoma of the skin in patients without apparent visceral involvement has already been reported.[4] Complete regression of five tumours in one patient has now lasted for a year.

H. R. BIERMAN and his associates (Bethesda and San Francisco) discussed the importance of the "tissue contact time" (T.C.T.), with special reference to the effectiveness of nitrogen-mustard therapy. There was an enhanced effect after intra-arterial injection of nitrogen mustard, but increase of the T.C.T., by occluding the venous return and arterial supply of a neoplastic area, combined with arterial infusion of the drug, was more effective. The optimal T.C.T. for each tumour and parent organ varied considerably, but experience with 20 patients with various tumours indicated that it was about 10–14 minutes with doses of nitrogen mustard of from 5 to 30 mg.

Experimental Pathology

H. W. TOOLAN (New York) reported results of transplantation experiments with 100 human tumours (including epidermoid carcinomas and adenocarcinomas of the thyroid and alimentary canal). 90% of these tumours "took" when transplanted into cortisone-treated rats. It seemed that some of these tumours could be maintained indefinitely if transplanted into successive series of cortisone-treated rats; one tumour was transplanted through 8 generations and is now being carried by 150 rats. Dr. Toolan hoped that enough animals bearing human tumours would shortly be available to permit new therapeutic agents to be tested against human, rather than animal, tumours.

A. C. GRIFFIN and his colleagues (Stanford, California) found that hypophysectomised rats, fed with azo-dyes, did not have liver damage or tumours. Extensive liver degeneration and cirrhosis, however, occurred when these rats were treated with the pituitary gonadotrophin fraction. This suggested that the factor or factors involved in this carcinogenic process were present in this fraction.

F. E. RAY and M. F. ARGUS (Gainesville, Florida) described work on the distribution of radioactivity after administration of a S^{35}-labelled sulphonic acid (disodium fluorene-2,7-disulphonate) to A-strain mice bearing a transplantable squamous-cell carcinoma. 2 hours after administration the concentration of radioactivity was greater in the tumour than in any organ; 8 hours later the concentration was still greater in the tumour than in the liver, spleen, and muscles, although slightly less than in the kidneys and blood. This compound was more favourable than the dyes previously used, and it was concluded that localisation in the liver and spleen did not necessarily accompany localisation of sulphonic acids in tumour tissue.

Reviews of Books

Clinical Neurology

FRANK A. ELLIOTT, M.B., F.R.C.P., assistant physician, Charing Cross Hospital; BRODIE HUGHES, CH.M., F.R.C.S., professor of neurosurgery, University of Birmingham; J. W. ALDREN TURNER, D.M., F.R.C.P., neurologist, St. Bartholomew's Hospital, London. Editor: FRANK A. ELLIOTT. London: Cassell. 1952. Pp. 751. 42*s.*

THIS textbook by two neurologists and a neurosurgeon has been primarily written, the preface says, for postgraduate students. The first section deals with disorders of the motor system, somatic sensation, mental disorders, and speech disturbances and the like, ending with a short description of ancillary diagnostic procedures (including neuroradiology and electro-encephalography). A concise account of the principles involved in the electrodiagnosis of neuromuscular disorders is contributed by Dr. A. E. Ritchie. The second section covers individual diseases. The book is readable, well coördinated, and written in a clear and concise style. The aim has been "to present the common problems of neurology within a reasonable compass and to avoid the rare, the recondite, and the contentious," and by and large the authors have succeeded well in this, though there are occasional lapses.

In the section dealing with vertigo, no mention is made of benign positional vertigo and vestibular neuronitis, both common causes of this symptom. Again, though radicular disturbances due to cervical intervertebral disc degeneration are discussed in detail, only scattered references are made to the more important symptoms due to involvement of the spinal cord. Cervical spondylosis, being such a common and important condition, surely deserves fuller differentiation from the other neurological disorders it may closely resemble.

Within the limits defined by the editor, the book provides an accurate and up-to-date summary of contemporary neurological knowledge, and of the methods of investigation and treatment of disorders of the nervous system in current use in this country. We recommend it warmly to those for whom it is intended.

The Psychologist Looks at Sex and Marriage

ALLAN FROMME, D.PH. Kingswood, Surrey: The World's Work. 1952. Pp. 230. 15*s.*

THE relief of finding a first chapter in a marriage-guidance manual headed "Personal Maturity" would in itself excuse Dr. Fromme for adding to a congested literature, even if his contribution were not outstandingly good. This is, in fact, a sane and useful book. He emphasises social psychology rather than physiology (which dominates the older books). His approach to psychodynamics is eclectic, anthropological, and above all sensible, and he deals well with the physical side of sex hygiene. The device of summarising the text in a series of generalisations printed as paragraph headings is irritating to the continuous reader, but facilitates reference.

This is a book in line with humanistic ethics, acceptable to educated patients and to those who educate patients.

The Bile Pigments

C. H. GRAY, M.D., D.SC., M.R.C.P., F.R.I.C., professor of chemical pathology, University of London. London: Methuen. 1953. Pp. 142. 9*s.* 6*d.*

THIS, the third volume of Methuen's series of monographs on biochemical subjects, is well up to the high standard of its two predecessors, Davidson's *The Biochemistry of the Nucleic Acids*, and Albert's *Selective Toxicity*. The subject is undoubtedly a difficult one, the chemistry complex, and the nomenclature not easy to follow. Nevertheless, in 15 small pages an unusually clear account is presented of the structure of bilirubin, the steps by which this was ascertained, and the relationships with most of its important chemical derivatives and precursors. Useful sections on the preparation and determination of bile pigments are appended. The subject matter is by no means confined to pure chemistry, and the author's clinical interests are clearly shown in his expert discussion of the van den Bergh reaction, the clinical varieties of jaundice, and the problem of urobilin and its precursors in urine and fæces. The account of the biosynthesis of the bile pigments incorporates the results of recent work using N^{15}-labelled glycine, to which Gray has himself made significant contributions. According to the information on the cover, the "aim of this brief monograph is to provide a readable, useful and brief account of the bile pigments." It does even more: it provides an excellent guide through the maze of recent work on this complex subject.

Biological Hazards of Atomic Energy

Editor: A. HADDOW. London: *Oxford University Press.* 1952. Pp. 235. 35*s.*

THIS book records the proceedings of the conference on the biological hazards of atomic energy held in October, 1950, at the Royal Institution. The 24 short articles are by leading authorities in the United Kingdom, and by three distinguished foreign visitors. For those biologists interested in the implications of nuclear energy, biologists or otherwise, they form a useful reference book. They provide a good summary of British views in October, 1950; and few of these views will have changed much since then.

which sister has some control If she is asked to economise in items which are displayed as a small percentage of total costs she may well feel "what's the use?"

Departmental Chiefs

Similar argument applies here Quantitative criteria of output—beloved of the cost accountant—can be irritating if applied too rigidly It is more important that the chief and his staff should, in their relations with patients, be free from "the insolence of office," than that their output in items of service be x% greater than last year

Each departmental chief can agree with the local administration on the most efficient method of presenting costs in his department Again, the apportionment of overheads to each department is of minor interest to its chief, compared with figures relating to expenditure controllable by him

Hospital Management Committees

These are in a position to review the costs of the running of the group as a whole, and of running the various separate clinics and hospitals within their group Statements are therefore required to show how the total budget is distributed over the hospitals and departments, how the various quantitative criteria are being applied (inpatient days, outpatient attendances, &c), and how the group stands in relation to projected improvements, alterations in structure, developments of particular services, and so on

At this level, the modes of apportionment of overheads and general services expenditure are of relevance The details of use to ward sisters are only relevant in the form of brief summaries of costs (carbon copies of such detailed statements can be available if required)

Comparative statements of costs as between groups may be of interest, but these are not the main concern of the hospital management committee, its own quality of service per pound expended is the main thing

Regional Hospital Boards

In the distribution of funds to the hospital management committees in the region, the equity (or otherwise) of the bases for allocation is of paramount importance As the regions contain hospitals varying so widely in their architectural efficiency (converted public-assistance institutions with acres of stone-flagged corridors can be expensive to paint, to clean, and to heat), their internal accessibility (inadequate lifts are the rule in old-fashioned buildings), and their capacity to attract efficient labour (compare the portering staffs at different hospitals), there are many problems to be solved before costing comparisons can be made between groups of hospitals with sufficient validity to justify their application in any system of budgetary control This aspect is discussed by Topping [4] in an instructive paper

Limitations of Costing Systems

The main object of costing analysis is to help the management to exercise control over expenditure, not merely to economise, but to obtain the maximum value for money The claims which are sometimes made for costing systems—that they bring into being a "new approach" which enables one to plan the future in a new and more efficient way—are, in my opinion, not free from inflation with the wind of enthusiasm

A little reflection will show that, under the (admittedly not-fully-informative) system at present in use, management committees do in fact plan their future use of funds, assign priorities, and generally apply intelligent forecasting to the running of their hospitals The proposal to analyse costs a little further so that departmental costs will become available, will not revolutionise the situation, it will simply allow the accumulation of more detailed comparative cost-information How much use (or misuse) is made of this information will depend upon how much careful analysis is applied to the schemes of costing experts when these are examined in the administrative departments of the health service My object in writing this article is to provide a corrective to any too-enthusiastic adoption of detailed schemes

It will be necessary to urge some form of corrective restraint for the experience of the business world has shown that fashions for "systems" develop and hold sway for considerable periods, enthralling those who fall a prey to slogans like "budgetary control," and leading some (otherwise highly intelligent) people to think and believe that in some way the application of such and such a system will automatically reduce costs, increase income, abolish waste, and generally change the whole financial situation!

One kind of fallacy which can easily arise is well illustrated by a problem which occurred when a syringe service was being costed in the course of its planning on paper A centralised syringe service in a hospital removes from the wards and clinics the work of boiling-up syringes and needles, and substitutes centralised sterilisation with a collection and delivery service A simple calculation based upon the number of syringes used per day in each ward and clinic, and the value of the nurses' time thus saved, enables one to show that the annual saving thus effected goes far towards paying for the labour and materials required by the centralised packing and sterilising unit But is this a valid calculation? It is not A little thought will reveal that although indeed a large number of nurses will have a few minutes more time each day available for their other multifarious duties, this time saved will not affect the number of nurses required in any one ward or clinic, and so no *financial* saving will be made The proper way of describing the effect of the installation of the central syringe service is to point this out, and to recognise that the extra cost of the service has to be regarded as the price paid for greater assurance of sterility in the syringes and needles, and some slight reduction in the burden of work upon the nurses I would ask my colleagues to ponder this simple illustration, and to realise that this type of fallacy easily arises in discussions about comparative costs

A hospital laundry may be housed in part of the hospital premises, and its total costs, after charging to it a reasonable hypothetical rent for the premises occupied, may prove to be excessive compared with what would be charged by an outside contractor for the same volume of work. If, however, the premises once occupied by the laundry would in fact remain unused, if the laundry work were done by an outside contractor, then the result of the change might not be a saving, but a loss Nevertheless, it is entirely proper to charge the laundry with a reasonable hypothetical rent, for only thus can the total cost of the laundry be ascertained if comparison with outside contractors is desired Such a comparison may help to initiate inquiries as to the reasons why the costs, other than rent, are excessive

Summary

The introduction of departmental costing in the day-to-day accounting systems of hospitals will help to provide the additional information which is necessary before any rational comparisons can be drawn between expenditures at different hospitals

Such a change will in fact amount to an extension of the present system of analysis If adopted, it will not be a radical or revolutionary change, and it will not automatically solve major problems or cut costs, it will itself cost money

The application of the results of departmental costing will yield information of value, but the interpretation of the figures and the use made of them will call for close scrutiny by all involved—not least by the doctors

Such a scrutiny is perfectly feasible if the fundamentals be kept in mind, no one should be dissuaded from taking part merely because he feels himself a layman in respect of costing systems I would especially ask my colleagues to read what McLachlan [5,6] has written on the limitations of purely financial indices in the health service

Finally, I would plead for active coöperation between doctors and finance officers, so that the final forms of analysis adopted may reflect, not the wholesale application of an elaborate conventional costing system, but rather the recognition of the special problems of hospitals and the variety of indices which can prove helpful

THE LANCET

LONDON: SATURDAY, MAY 16, 1953

Protection of Children

OUR most commonly used legal remedy for relieving an ill-used child is to take him away from his parents and put him with well-meaning strangers. The notion that the separation of a child from his mother is in itself an extremely damaging form of ill-usage is only just beginning to penetrate medicine, and will therefore take some time to influence the law. Under the Children and Young Persons Act, 1933, cruelty to persons under 16 is defined as follows:

> "If any person who has attained the age of sixteen years and has the custody, charge or care of any child or young person under that age, wilfully assaults, ill-treats, neglects, abandons, or exposes him, or causes or procures him to be assaulted, ill-treated, neglected, abandoned, or exposed, in a manner likely to cause him unnecessary suffering or injury to health (including injury to or loss of sight, or hearing, or limb, or organ of the body, and any mental derangement), that person shall be guilty of a misdemeanour . . ."

The Act does not make it clear whether "mental derangement" is confined to conditions accompanied by psychotic symptoms, or whether treatment likely to cause neurotic symptoms is also an offence. In the latter case, the court ordering separation must, on occasions, surely qualify as an offender. Nowadays cruelty need not even be "wilful": under the Children and Young Persons (Amendment) Act of 1952, a child may be removed by a court from his parents on grounds of ill-treatment, neglect, and so on, without its being necessary to show that his parents, or other custodians, have *intentionally* misused him. This means that the child may suffer not only the hardship caused by the offence, but the more severe and prolonged hardship of separation from a mother who may never have meant him—*or indeed even done him*—any harm. The Children's Officers Association, who have set out these facts and many others in a thoroughly sound memorandum, *Cruelty to Children*[1] (prepared at the request of a joint committee of the British Medical Association and the Magistrates' Association), say:

> "Our members know of cases where children have been brought before courts as being 'in moral danger' where the evidence was that the father bullied and terrified children and mother. In such cases the offender has gone unpunished and the very severe punishment of being taken away from their mother has been meted out to the children. In some cases the children (in spite of their alleged unhappy situation with their parents) have been known to scream and fight with the officers of the court who are removing them from their mother. Arrived at the institution they pine for their own homes. Such experiences may damage the children permanently."

The humane desire to protect children from cruelty began to show itself publicly in the last century, when the Industrial Revolution was causing growing numbers of children in mines and factories to suffer hunger, stunting, or disease, as well as bodily distress at the hands of hard masters or of despairing and drunken parents. Their suffering was occasioned mainly by *physical* violence, *physical* deprivation. The memorandum points out that this scene has now changed. The incidence of assault and undue restraint of children has diminished over the last half-century; it is mainly associated with drunkenness, which has also declined. Moreover the association believe that the machinery for detecting and combating physical violence against children is adequate. "The prevention of mental ill-treatment," they say, "is a much wider problem, and one in which a lead can only be given by the medical profession."

The law is certainly very uneven in its operation. Thus the mentally subnormal mother of a large family who loves her children but lets them get dirty and ill-nourished can be punished (for her incompetence rather than her fault) by imprisonment, or by having her children taken from her. In either case the children suffer harm. Excuses are found, however, for the unmarried father and mother who have a child and fail to arrange a secure upbringing for him. Again, a father can be convicted and imprisoned for a single blow delivered in a rare bout of drunkenness; but a father who wilfully spends his earnings on something other than the rent, and gets his family evicted and his children into institutions, at once becomes better off financially than his more responsible neighbours who still have children to keep. The children's officers, however, think something might be achieved immediately by a more flexible use of the law. Parents convicted of a first offence, especially of neglect, should be severely warned that another conviction will mean imprisonment, and then be sent home on probation. At present children are almost automatically committed to the care of a local authority whenever an offence is proved: the provision for placing them under supervision at home, and for taking recognisances from the parents, could, the association believe, be much more widely used. But if the parents have behaved so badly that the children *must* be taken away, then "a very substantial contribution to their maintenance" should be required from the parents. Sometimes the most constructive thing to do is to sentence the principal offender (who is usually the father) and send the children home with their mother. She will sometimes need help from the citizens' advice bureau in proceedings to ensure that the father never returns home; and she will often need the help of the domiciliary services—the health visitor, the home help, the school welfare officer, and perhaps the family service unit. Sometimes a neglectful mother can profit by the kind of training given in hostels such as the Brentwood and Mayflower homes, where she and her children can stay while she learns the rudiments of house management and child care. The first object, however, should always be to save the existing home, and keep the father and mother together, rather than to send either parent away.

This may sound a costly proceeding in terms of social services; but it would in fact, the children's officers point out, be a good deal cheaper than our present practice. To maintain one child for a week in a children's home may cost as much as £5; in an approved school more than £6; in a residential nursery as much as £8. One child in institutional care for fifteen years may cost up to £3000, and the outlay for a large family runs into five figures. "A tithe of

INSTITUTE OF HOSPITAL ADMINISTRATORS

THE institute held its annual conference at Hastings from May 7 to 9.

Training of Administrators

In his presidential address, Mr. S C **MERIVALE**, secretary to the board of governors of the United Bristol Hospitals, examined the ways in which hospital administrators are at present learning their jobs The institute itself made arrangements for systematic instruction and examination for its diploma , and there was the Hospital Administrative Staff College in London, where King Edward's Hospital Fund provided special facilities for concentrated postgraduate study In addition certain hospitals throughout the country were working schemes for the instruction of one or more trainee administrators There were, Mr. Merivale thought various dangers in this situation For one thing, "private enterprise" schemes might remain both too "private" and too "enterprising" "too private" because such schemes would tend to turn out people purporting to be fully trained when they had had experience of working in only one hospital group or authority , "too enterprising" because such uncoördinated individual efforts might lead to over-recruitment of able people and a glut of "registrars" in the administrative branch of the service Another danger was that the Administrative Staff College might lose some of its effectiveness by an inability to link up the work which only it could do with approved practical work in the widest possible variety of hospitals and hospital authorities. The institute and its regional councils could play a big part in arranging in coöperation with hospital authorities and the staff college, training circuits to which people who were prepared to make the necessary sacrifices could enter from within the service These arrangements could and should be linked with the Recruitment Advisory Service which the King's Fund had already set up at the college

To overcome the difficulties involved in moving trainee staff about the country, Mr. Merivale proposed that there should be in every region a sort of Civil Service Commission for the administrative branch of the health service, containing representatives of the regional council of the institute and the employing authorities This body would approve appointments for designation [illegible] o six of which would be grouped [illegible] to provide the widest possible variety of experience These posts would be held for from six to twelve months each, and they would be linked with the staff college to ensure that a period of concentrated study and instruction was included in the normal progress round a training circuit The number of posts in each circuit should bear some relation to the ultimate prospects of their holders, bearing in mind the number of senior appointments that would be available As Mr Merivale pointed out, these proposals to some extent involved individual authorities voluntarily surrendering their present sovereign rights to make their own administrative appointments at "registrar" level. But if the administrative service was to compete successfully for its share of the best recruits, its training arrangements must bear comparison with those in other walks of life and the prospects of promotion must be fair and reasonable The need, therefore, was for some practicable and acceptable compromise between the present haphazard system and its opposite—promotion by posting

The Committee System

Mr **JOHN TREVELYAN** discussed the advantages and disadvantages of the committee system, with particular reference to its place in hospital administration Committees tended to discourage action as the anonymous cynic put it; "a committee is a group of men who individually can do nothing but collectively can meet and decide that nothing can be done." Sometimes, too, the power of decision on technical matters rested with the inexperienced On the other hand these were not always disadvantages for precipitate action was not always a good thing and in these days of specialists in every field often with competing claims, the judgment of the non-specialist might be valuable in maintaining a balance Moreover, history had taught us that the committee system, however cumbersome it might be, was an effective barrier to tyranny , and in our time we had to fight against the tyranny not of the autocrat, but of the bureaucrat In the hospital service executive responsibility was shared between the Ministry and the various committees—from regional hospital boards to house committees—in varying and not always clearly defined, proportions It produced the problem of how to blend central direction with decentralised committee administration , there was the danger of too much central direction largely in the form of a tight financial rein Remote control often led to standardisation and discouraged variations in individual hospitals

Turning to possible improvements in the system, Mr Trevelyan thought that there could usefully be more building from the perimeter to the centre For example, in the teaching hospital groups each board of governors might consist of some members appointed by the Minister and others elected by the house committees of the hospitals in the group Similarly, each regional hospital board might consist of a certain number of members appointed by the Minister and other members appointed by the hospital management committees in the region and each hospital management committee might be constructed in much the same way This process might be developed further by establishing a Central Hospitals Service Committee, with some members appointed by the Minister and some elected by boards of governors and regional hospital boards. Such a committee could represent the committee administration of the service in discussion with the Ministry and coöperate with the Minister in determining policy In this way all parts of the hospital service down to the committees concerned with individual hospitals could share in policy-making Further delegated authority should be progressively increased and should include as much financial responsibility as possible It was to be hoped that the new committee which was to investigate the cost of the N H S would see that the best way to save money on the hospital service was to trust the people who were running it The individual hospital committee should be given as much responsibility as possible, and it was no good having committees that had no responsible job to do In the details of committee work committees should consider what executive responsibility could be entrusted to their officers , it was up to the committees to see that they did not waste time discussing matters which could and should be dealt with by their officers. Mr Trevelyan summed up with the words of Anthony Ashton "The Committee is one of man's important social discoveries—like the use of money, the rule of law and the specialisation of labour—but it is not a panacea To solve problems it is not enough merely to set up committees They can moderate and guide the creative energy of individual men, but they can never be a substitute for it"

The Changing Function of the Hospital

Tracing the changes in the work of the hospital, Dr H W C **VINES** professor of pathology at Charing Cross Hospital Medical School, deplored the trend which was making the hospital more of an administrative unit and less of a place where patients were cared for The patient was being overlooked , and there was the money spent on maintaining neglected children in institutions apart from their parents could provide, throughout the kingdom, a first-class family service which would considerably reduce the incidence of neglect." The association offer some economic propositions which they regard as axiomatic:

> Children should not be removed from home simply for failure to attend school (it is less costly to send the school attendance officer to fetch them every day); or because their mother is ill (it is cheaper to put in a home help); or because their home is dirty (it is cheaper to put in a family service unit); or because the house is overcrowded or insanitary, or because there is no house (it is cheaper to provide a house); or because their mother is widowed, unmarried, or deserted and so has to go out to work (it is cheaper to pay an adequate allowance from National Assistance to keep her at home with them).

Their long-term remedies read, the association admit, like a prescription for the sickness of society. They are: to strengthen the churches and other organisations promoting the social virtues; to provide enough psychiatric and child-guidance and marriage-guidance clinics; to give people education in citizenship and parentcraft; to build enough houses; to extend domiciliary social services, services for unmarried mothers, health services for overburdened mothers, and educational services for handicapped children; and to ensure skilled social work in the matrimonial courts when families are breaking up, so that the court's decision is consonant with the welfare of the children. In cases of cruelty, the courts should always insist on exhaustive inquiries before breaking up the family; for "the removal of a child from his home is a dangerous and costly expedient which should only be resorted to after all other means of ameliorating his hardships have failed."

Cerebral Angiography

CEREBRAL angiography is now widely regarded as one of the most important accessory methods in the diagnosis of cerebral lesions. Percutaneous injection of contrast material into the carotid artery was first carried out by EGAS MONIZ,[1] to whom credit is due for much experimental work in angiography. In 1926, using a solution of 70% strontium bromide, MONIZ attempted cerebral angiography under local anæsthesia on four patients, but the results were unsatisfactory and thereafter he turned to injection after surgical exposure of the carotid artery. The introduction in 1931 of a colloidal suspension of the dioxide of thorium ('Thorotrast'), a non-irritant opaque contrast medium, gave further impulse to his work; and in 1932 the first carotid angiography in this country was done at the National Hospital, Queen Square, by MONIZ's pupil and successor, Prof. ALMEIDA LIMA. In the ensuing years cerebral angiography passed beyond the experimental stage; but it came under a cloud when NORTHFIELD and RUSSELL[2] and other workers demonstrated the potential dangers of thorotrast as a contrast medium. Thereafter for some years in this country carotid angiography was employed only when essential information could not be obtained by other methods. LIMA,[3] however, continues to use thorotrast as a contrast medium, on the grounds that it is non-irritant and will not produce vascular spasm. He claims that if the dose is limited to 16 ml. the risk from its radioactivity is negligible.

In Sweden interest in the subject continued during the war years and resulted in the establishment of a satisfactory percutaneous technique for injection of the carotid artery with diodone as a contrast medium. ENGESET[4] was largely responsible for this development, which revived interest in the procedure after the war. TORKILDSEN[5] described results in a series of over 2000 examinations, and BULL[6] in over 1000. LINDGREN[7] in Sweden, SUGAR et al.[8] in the U.S.A., and SUTTON and HOARE[9] in this country described the technique of percutaneous injection of the vertebral artery for the purpose of demonstrating lesions in parts of the brain not shown by carotid injection. RADNER[10] developed another technique for injection of the vertebral artery, by catheterising the radial artery. ECKER[11] and KRAYENBUHL and RICHTER[12] advocate the commoner percutaneous method, and claim that with efficient technique the risk is small. PETIT-DUTAILLIS et al.[13] have reviewed their own results with this method in over 1000 cases. They, too, believe that good technique will prevent untoward after-effects, and have observed "transitory and regressive incidents" in only 0·6% of their cases.

There is, however, some evidence that both method and contrast medium are not devoid of risk to the patient. Several workers have reported serious sequelæ. DUNSMORE et al.[14] feel less sure that technical efficiency is a guarantee against complications, and suggest that the delay in the appearance of the more serious reported complications points to their resulting from thrombosis following vasospasm, especially in patients with impaired circulation. These workers also point out the risk of injury to the cervical sympathetic chain if extravasation of the contrast medium occurs. After-effects of the intravenous injection of diodone have been described in these columns.[15]

Percutaneous cerebral angiography is an important diagnostic procedure, but its advantages should not obscure the fact that it involves the puncture of relatively small arteries by a "blind" technique and injection of a substance known to produce vascular spasm. Experienced workers admit that not uncommonly both walls of the artery may be punctured before the needle is surely in the arterial lumen. The subsequent effects on the arterial wall are still unknown. Until a non-irritant water-soluble contrast medium, which is rapidly excreted, is found the risk to a patient with arterial disease or a cerebral lesion likely to be aggravated by vascular spasm must be very carefully weighed against the value in treatment of the information likely to be obtained. The techniques of percutaneous arterial puncture and injection demand long training and continuous experience, not of a single

even a danger that standards of hospital care would be determined by those who had never seen a patient and who would be no wiser if they did Professor Vines confessed that he was bored with the massive and uninformative financial statements that came from the hospitals, for they gave very little indication of the efficiency with which the patients were being cared for, and they certainly did not take into account the potential financial return achieved by the hospital service when it restored its patients to work—a return which was forgotten when urging economies in the service He could see no very vivid future for the hospitals now that the inspired service of their earlier days had given place to a mediocrity oppressed by bureaucracy

Emphasising the need for a more preventive approach, Professor Vines said that a large burden of national sickness had long been accepted as inevitable, and this burden was a measure of society's failure to provide for healthy living There was still little professional interest in preventive medicine, and the bed remained the chief operational tool of the hospital service On the administrative side, too many administrators thought that the care of inpatients was their only job, whereas in fact the outpatient department often afforded a much better chance of preventing serious deterioration in health But little money was spent on outpatient departments, and present conditions encouraged the admission of outpatients when a really efficient outpatient department might have saved a hospital bed and the expense of inpatient care It was said that we needed about 75,000 more hospital beds in this country to build and pay for these beds in the next fifty years was probably impossible, to staff them was almost certainly impossible, and it was very doubtful whether we could afford to maintain them even if we had them Professor Vines was sure that successful development did not lie along the unimaginative lines of building more and more beds These missing beds must be written off, and the bed must recede as a therapeutic weapon, while the outpatient department came forward We must reduce the no man's-land between health and disease by persuading the patient to seek earlier advice and by encouraging a more inquisitive outlook by the doctor More ambulant patients and more outpatient work should be the aim Along these lines, the polyclinic might become the centre of the hospital service This would involve a complete reorientation of medical thought, and the first step was a drastic overhaul of outpatient clinics—not just a bit of paint here and there, but replanning and rebuilding Many "hole-and corner" clinics would have to go No hospital should offer an outpatient service without adequate radiological and pathological facilities immediately to hand to save the time of both patients and staff Fluoroscopy rooms and pathological "sub stations," which would relieve the main departments of much routine work, could be usefully introduced into the plan As the emphasis of the hospital service moved from beds to outpatient clinics, more of the bedded hospitals might be situated in the outskirts of towns, leaving the unbedded clinics in the centre

Opening the discussion, Mr S W **Barnes**, secretary to the board of governors of *King's College Hospital*, said that no-one regretted the domination of administration, to which Professor Vines had referred, more than the hospital administrators themselves They did not like the cold, impersonal, centralised machine, and they were not responsible for it, it was the outcome of a central bureaucratic control which knew little of actual conditions in hospitals Commending Professor Vines's proposals for extending the outpatient service, Mr Barnes said that all would be wishful thinking unless the control of policy and finance by the Government could be reconciled with independence and variation in individual hospitals Mr W A **James** (Leamington) wondered whether advances in treatment might not help matters by enabling a reduction to be made in the number of beds for acute cases But Professor Vines was not sure that such a reduction would be an advantage, for the chronic sick of tomorrow were the treatable sick of today Mr F A **Weaver** (Windsor) suggested that the medical staff of the hospital service were terrified of making a diagnosis because of the threat of litigation They tended to "pass the buck" in a way which complicated the working of the service Mr S G **Hill** (Northampton) would have liked Professor Vines's criticisms to have been heard by the Ministry of Health, the local health authorities, and the doctors, for preventive medicine was not the business of the hospital administrators, or even of the hospitals, and the preoccupation with inpatient beds was the result of the Ministry's attitude

---

JOINT CONSULTANTS' COMMITTEE

This committee met in London on April 29, under the chairmanship of Sir Russell Brain, F R C P

The committee again discussed the senior-registrar establishment, with particular reference to displacement Figures furnished by the Ministry of Health showed that the number of senior registrars did not now greatly exceed the establishment agreed with the committee in 1951 The number of senior registrars in their fourth or subsequent years, however, whose appointments were due to be terminated in the course of the next few months, substantially exceeded the expected consultant vacancies, and furthermore a large proportion of these senior registrars were in general medicine and surgery, in which specialties there were few new consultant appointments

Representatives of the committee had impressed upon the Ministry that many of these senior registrars were in fact undertaking consultant work, and that if they were dismissed a serious situation would arise They had again urged that the ultimate solution lay in the expansion of the consultant establishment, and they had made certain suggestions regarding immediate measures which the Ministry had received sympathetically It is hoped that a further statement on the subject will be available for publication shortly

The committee also considered a report from a subcommittee on discussions with representatives of the medical defence organisations on the increasing litigation involving members of hospital staffs

Pending further discussions with the Ministry, the committee expressed full agreement with a statement on the subject which had been drafted by the Central Consultants' and Specialists' Committee with a view to publication by the council of the British Medical Association The committee's attention was drawn to a statement on the furnishing of medical reports on hospital patients to solicitors, published in the *Law Society's Gazette* after discussions between the council of the Law Society and the Ministry The committee deprecated the issue of this statement without consultation with the medical profession, and the statement was referred to a subcommittee for detailed examination

Dr Peter Edwards, chairman of the tuberculosis and diseases of the chest group committee of the British Medical Association, attended the meeting to discuss matters of interest to chest physicians

Dr Edwards said that in most other specialties hospital boards often offered consultants an option of whole time or part time service, where the needs of the service permitted, and the group committee felt that this principle should be applied to chest physicians The Chairman explained that this matter had already been discussed with the Ministry, but there appeared to be certain difficulties connected chiefly with the duties carried out by chest physicians on behalf of local health authorities The matter was referred to a subcommittee for further discussion with the Ministry

Dr Edwards also expressed the views of his group committee on the shortage of nurses in sanatoria, and on the participation of chest physicians in the work of pneumoconiosis panels, and these matters also were referred for discussion with the Ministry.

operator but of a team comprising radiologist, radiographers, and nursing staff. Thus the method should be used only with due regard for its possible risks and in centres where the necessary skill and experience are available.

Ophthalmia Neonatorum

In 1884 the Ophthalmological Society of the United Kingdom reported that of the inmates of four representative institutions for the blind between 30 and 41% had lost their sight because of ophthalmia neonatorum. In the U.S.A. the percentage seems to have been somewhat greater, and in Continental countries much greater.[1] In 1922 a Ministry of Education survey of provincial schools for the blind showed that 30·4% of the inmates had been blinded by ophthalmia neonatorum: but by 1944, after twenty-two years of compulsory notification, the proportion had fallen to 9·2%.[2] In 1947 Sorsby[3] stated that in the years 1941–45 only 5 infants in England and Wales were known to have lost their sight in this way, and since then no case of blindness from this disease has been brought to the notice of the Ministry of Health. Ophthalmia neonatorum continues to be notified, though in decreasing numbers (4390 cases in 1940, 1935 cases in 1950); but serious ophthalmitis, and in particular gonococcal ophthalmitis, is now exceptional in maternity and eye hospitals in this country.

Benjamin Gibson, of Manchester, was one of the first to associate neonatal ophthalmia with maternal vaginal discharge. In 1807 he suggested[4] three steps to prevent it:

> "First, to remove, if possible, the disease in the mother during pregnancy; secondly, if that cannot be accomplished, to remove artificially as much of the discharge as possible from the vagina at the time of delivery; and third, to pay, at all events, particular attention to the eyes of the child by washing them immediately after delivery with a liquid calculated to remove the offending matter or to prevent its noxious action."

The elimination of blindness due to ophthalmia neonatorum is clearly the result of action such as Gibson advised, and the present low prevalence of maternal gonococcal infection must be the most important single cause. Local hygienic measures, which are undoubtedly valuable, are applied routinely; but prophylactic conjunctival instillations are no longer made universally. In 1948 a committee of the American Academy of Ophthalmology and Otolaryngology[5] reported unanimously in favour of such applications, preferably with silver nitrate; but in Britain practice has been changing. Elliott[6] found last year that in 50% of maternity units this step had been abandoned, and among 40% of local health authorities "no chemicals were in use as a routine measure." Impetus has been given to this trend by a bacteriological investigation at Queen Charlotte's Hospital in 1948: in their study of 220 infants Taylor and Calman[7] found that the rate of infection with any organism was not greatly different in eyes treated with silver nitrate from the rate in untreated eyes. These workers concluded that, in view of the effectiveness of modern treatment of established ophthalmia, it was probably unnecessary *in that hospital* to instil any form of eye-drops.

Silver-nitrate drops have an ill repute as a conjunctival irritant. When the solution is applied in the prescribed strength and amount, this irritation is usually mild and transient; but when by evaporation it becomes concentrated, or by actinic action decomposed, severe ocular irritation and serious damage may ensue. Several alternatives have been tried, including silver proteinate,[8] mercurochrome,[9] and acriflavine.[10] By far the most effective, however, is penicillin, which is now widely used on the Continent, in North and South America, and elsewhere. (In this country investigations have been concerned mainly with its value in established ophthalmia neonatorum.[8]) For prophylaxis an aqueous solution, usually in a strength of 2500 or 5000 units per ml., is instilled one or more times, either alone or after saline irrigation of the conjunctival sac. Sensitisation has not so far been noted; but repeated instillations call for increased nursing attention, and neonatal ophthalmia has not been wholly eliminated by them—it is perhaps too much, as Sorsby[3] has pointed out, to expect that a single drop of penicillin should sterilise the infected conjunctival sac. Intramuscular injection of penicillin has proved more successful: but this entails medical attention and a definite risk of sensitisation. Furthermore a fatal Herxheimer reaction may ensue: Woods[5] refers to 3 cases in which syphilitic infants died after prophylactic intramuscular injections of penicillin. Oily suspensions or ointments are more reliable, if their penicillin content is great enough. Davidson and his co-workers[11] at the Johns Hopkins Hospital compared the effect of an ointment containing 100,000 units per gramme, applied once at birth, with that of intramuscular injections of 10,000 units of penicillin, and of silver nitrate instillations. They found that the ointment was no less effective than penicillin given intramuscularly; and in the two groups treated by these two methods signs of conjunctival irritation or frank discharge were significantly less common than in the group treated with silver nitrate. The prevalence of maternal gonorrhœa at that time was estimated at 2·7%, but serious ophthalmia neonatorum was not encountered in any of the three groups. More recently Mallek and his co-workers[12] in Vancouver have come to similar conclusions. In one group of their series an ointment containing 2500 units per gramme was applied repeatedly. They attribute lid irritation seen in this group, but not in another treated once only with a more concentrated ointment containing 100,000 units per gramme, to trauma from repeated application.

There is thus good evidence that in prophylaxis, application of a potent penicillin ointment should replace silver nitrate; and the theoretical objections that not all organisms giving rise to neonatal ophthalmia respond to penicillin seems to weigh lightly in the opposite scale.

Other matters considered by the committee included reports of discussions with the Ministry on the hospital medical staffing survey and security of tenure, and questions relating to medical advisory machinery and the domiciliary-consultation arrangements Points relating to terms and conditions of service were referred to the staff side of Committee B of the Medical Whitley Council

IMPERIAL CANCER RESEARCH FUND

THE Fund's fiftieth annual report has lately been published [1]

The many interesting lines of study that are being followed include experiments on the heterotransplantation of human tumours, where the possibility is being examined of culturing human tumours in the eye of the guineapig and in the mouse's brain, along the lines worked out by Greene at Yale The capacity for survival of the graft under such adverse conditions has been to some extent correlated with the malignancy of the tumour

Dr JAMES CRAIGIE, F R S , has continued his researches on ascites tumours One of the aims of this work is to make available transplantable tumours which can be studied in a more quantitative way

> An ascites sarcoma induced in a C_3H mouse by benzpyrene has been shown to be transplantable with doses of less than 100 cells, "the dose required to produce ascites tumours with S 37 or T 2146 is 10,000 to 100,000 times greater than this One sub line of this tumour has practically lost its ability to form solid tumour and peritoneal invasion rapidly follows subcutaneous inoculation "

Dr B D PULLINGER is studying spontaneous mammary carcinoma in the R IIIb strain of mouse, which is carried on *without* the intervention of the milk factor

Work on fowl tumours has been started once more in the Fund's laboratories

> The incidence of neoplastic diseases is greater in the fowl than in man, and is the most important cause of death in fowls in countries with highly developed poultry industries "A large-group of these diseases, known as the leukosis complex, includes a great variety of neoplastic conditions which arise from alterations of cells of the blood, bone marrow, reticulo endothelial and lymphatic systems In some ways they are analogous to the leukæmias of man " Experiments are under way on a still undecided question—whether fowl lymphomatosis is transmitted by the living lymphoid tumour cell, or by a highly labile virus which so far has eluded all attempts at isolation

Mr P C WILLIAMS has been investigating the response to œstrogen of spayed mice of the C_3H, Strong A, and C_{57} strains, he finds that the vaginal œstrogen sensitivity is inversely related to mammary cancer incidence in these three strains Moreover, there is no obvious correlation between vaginal opening and mammary development, for the vagina opens earliest in the Strong A mice, but their mammary glands develop latest

Dr J STRATTON YOUNG and Dr G D LUMB have undertaken a study of human breast cancer from anatomical, histological, and cytological aspects, and by an examination of the hormonal status of postmenopausal patients with the disease

Dr L M FRANKS found, from a study of 150 prostatic glands removed post mortem, that histological evidence for malignancy could be shown in one third After œstrogen therapy of well established primary carcinoma of the prostate, insensitivity developed in the cells of the growth, which reverted to its former malignant structure The epithelium of the prostatic urethra, however, continued to show the metaplastic change induced by the œstrogen

Mr W H W JAYNE has been using tissue culture technique in order to determine the real nature of the cells in pleural exudates in suspected bronchial cancer

Mr H G CRABTREE has continued his studies on azo-dye carcinogenesis

> The effect of diet on the induction of liver tumours by various azo compounds, particularly 4 dimethyl amino-azobenzene (" butter yellow "), has been the basis of many investigations into the nature of the dietary factors giving protection against this form of carcinogenesis Attention was from the first focused on the B group of vitamins, since tumours originally described by Japanese workers were induced by the azo compounds in animals maintained on a diet of polished rice It was soon evident that aneurine alone was not the protective factor Yeast and liver-extracts were found to be protective, and Kensler showed that riboflavine (vitamin B_2) had a definite protective action against butter yellow carcinogenesis in rats maintained on diets of medium protein content but not on low protein diets The nature of the protective action appears therefore to be complex, and it is now realised that vitamins, proteins, and fats may all be involved

In this year's report Crabtree describes experiments which, he suggests, implicate yet another member of the vitamin-B group

> His work on the relative carcinogenic activity of amino azotoluenes led him to the conclusion that those compounds of this series which failed to induce liver tumours in rats are metabolised in the liver to *p* toluidine, which then gives rise to *p* aminobenzoic acid *p* Aminobenzoic acid is probably a precursor of folic acid, and the suggestion is that the *p* aminobenzoic acid, or more probably folic acid, is a protective factor against azo dye carcinogenesis Experiments to test this idea were described in last year's report, and more complete results are now given *p* Aminobenzoic acid itself failed to protect, but it is thought that effective concentrations of the vitamin in the liver may not be obtained by its addition to the diet, and Crabtree has fed animals with azo compounds designed especially to be metabolised in the liver to yield *p* aminobenzoic acid, thus producing a high concentration of the vitamin in that organ These azo compounds, when added to the food of rats in conjunction with butter yellow or *o* aminoazotoluene, significantly retarded the average rate of induction of liver tumours by these carcinogens

The results are interpreted by Crabtree as evidence " that the metabolism of *p* aminobenzoic acid (and possibly folic acid) may have particular significance for the mechanisms of carcinogenesis "

PROVINCIAL TEACHING HOSPITALS

Boards of Governors

THE Minister of Health has made the following appointments, to fill vacancies caused by the retirement of a third of the members, to the boards of governors of the ten provincial teaching hospitals in England and Wales Out of 92 appointments, 61 are reappointments of retiring members , 2 appointments are still outstanding Those now appointed will hold office until March 31, 1956 The names of medical members are given in bold type

UNITED NEWCASTLE UPON TYNE HOSPITALS

Reappointed Prof **R V Bradlaw,** O B E , F R C S , L D S , Edward Foyle Collingwood, C B E , J P , Prof **R Bramble Green,** F.R C.S , Prof **F J Nattrass,** F R C.P , Edward Colgan

New members **Norman Hodgson,** F.R C S , Rev R E Robson, J P , Miss A M Truesdale, B SC , G Hodnett, **James Hendry,** L R C P E

UNITED LEEDS HOSPITALS

Reappointed Alderman D Beevers, O B E , LL D , J P , Prof **A M Claye,** F.R C O G , Councillor W Maldwyn Jones , J E Rusby, M C , J P , Miss E G Lupton, M A , LL D , J.P , Prof **T Talmage Read,** F R.F P S , F D S R C S **Donald Watson,** F.R C S

New member Prof **P J Moir,** M C , F.R C S

UNITED SHEFFIELD HOSPITALS

Reappointed A R Martin , T Pearson, J.P , **H. R Vickers,** F R C.P , Prof **E J Wayne,** F.R C.P , J M Whittaker,

Annotations

RADIOGRAPHIC ENLARGEMENT

In ordinary radiography the sharpest definition is obtained by placing the film as close as possible to the object that is being radiographed, and the X-ray tube a good distance away from the object—hence the term "teleradiography." By moving the film away from the object a radiographic enlargement can be obtained, but use of an ordinary X-ray tube with a focal spot 1·0 sq. mm. for making such an enlargement entails a loss of definition. However, with a focal spot 0·3 sq. mm. —i.e., practically punctiform—and with both the X-ray tube and the film 24–30 in. from the body (and on opposite sides thereof) definition is remarkably good. Bronchograms taken by this method, which the French call "*radiographie en gros plan*" (a term borrowed from the cinematograph trade), have been exhibited in Paris,[1] and some excellent examples have been published.[2] Part of the secret of such bronchography is to use, as the radio-opaque medium, a mixture of 'Lipiodol' and either sulphanilamide or pure talcum powder, which fills the bronchial tree slowly and leaves on the bronchial wall a thin layer that shows up the smallest folds of mucosa. Apart from bronchography twofold radiographic enlargement can be applied to the lungs with advantage, both rendering the details much clearer than in ordinary radiographs and making more transparent the shadows of the intervening ribs. It is therefore especially useful in depicting miliary lesions and scars; but in the study of cavities tomography still reigns supreme.

Radiographic enlargement must not be confused with photographic enlargement; the former enlarges the X-ray shadows before they are fixed on the film, whereas the latter enlarges the picture already fixed on the film and therefore enlarges also the emulsion grains of the film and any flaws in it. Barclay[3] got over this difficulty in photographic enlargement of X-ray films by using film emulsions of very fine grain; but such long exposures were necessary that the method, though useful for depicting histological specimens, proved unsatisfactory for routine radiography of patients.

Now it is suggested by Layani et al.[4] that the two methods of enlargement, radiographic and photographic, should be combined. These workers first obtain threefold enlargements by direct radiography and then make threefold photographic enlargements thereof, thus obtaining ninefold enlargements altogether, examples of which they publish.

TREATMENT OF LYMPHŒDEMA

In lymphœdema there is chronic swelling of the superficial soft tissues, owing to accumulation of extracellular fluid rich in protein. This may arise as a congenital, and rarely familial, disorder in which a sponge-like lymphangectasia distends the soft tissue; or it may follow damage to the lymphatic system by recurrent streptococcal infections (elephantiasis nostras streptogenes), surgical intervention, or filarial or neoplastic disease. Often, however, no cause can be found in young women in whom there develops a progressive, painless, firm œdema of the lower limbs—a disturbance termed lymphœdema præcox.

The treatment of the lymphœdematous leg in the early, and often reversible, stages of the swelling is by firm support, preferably by a rubber bandage over a lisle stocking. Foot hygiene must be strict, and every effort made to eliminate recurrent streptococcal lymphangitis and interdigital fungus infections. Too often, however, the surgeon finds a massive limb which, in addition to its mechanical and cosmetic disadvantages, is recurrently attacked by a hæmolytic streptococcal infection.

Many ingenious operations have been designed to increase the drainage of lymph from the subcutaneous tissues, either into the deep tissues or into the abdominal wall. All have proved disappointing. Operations designed, not to repair the physiological disorder but to excise as much as possible of the abnormal tissue, have proved more successful. The original Kondoleon operation has been modified by Sistrunk,[1] Homans,[2] Macey,[3] and others. In principle, these procedures consist in a staged excision of the thickened abnormal tissue between the muscle or the deep fascia and the skin. The skin is widely undermined for exposure and finally turned back on the denuded muscle or fascia as a graft. These operations should not be undertaken lightly, for the blood-loss and traumatic shock may be great and skin healing is often tardy, and subsequent recurrence of the swelling and streptococcal cellulitis are not uncommon.

Recently Pratt[4] has introduced a further modification of the Kondolen procedure by which, after preliminary reduction of the swelling by postural drainage, the skin over the swollen limb is removed with an electric dermatome to a depth of 0·43 cm. This thickness, he believes, removes epithelium but not the lymphatic-bearing portion of the skin. After radical excision of all remaining hypertrophied tissue, the skin grafts are stitched together and replaced on the denuded muscle. When healing has taken place, bandage support is continued. Pratt has done 25 such operations in the last three years, and in none has the swelling recurred. Unfortunately he does not give details of the types and the severity of the cases selected. Possibly this skin-graft technique will find a place in the treatment of some lymphœdematous legs, but we need more precise correlation of results with ætiology and pathology.

WORLD HEALTH ASSEMBLY

Last Monday the sixth World Health Assembly, in Geneva, elected Dr. M. G. Candau, of Brazil, to be the new director-general of the World Health Organisation. Dr. Candau is at present deputy director of the W.H.O. regional office for the Americas; and for two years up to March, 1952, he was assistant director-general of W.H.O. in charge of the department of advisory services.

When the Assembly opened on May 5 the delegates paid homage to the Burmese delegation, composed of Dr. U Ba Maung and Dr. C. C. Po, who were killed in an aircrash near Calcutta on their way to Geneva. In his valedictory address to the members, the outgoing president, Dr. Juan Salcedo, jun. (Philippines), drew attention to dangers facing the Organisation—namely, the delay by some countries in the payment of their contributions, and the cut of nearly half in the U.N. Technical Assistance Funds for W.H.O. Dr. Murched Khater, minister of health of the Syrian Republic, who is the president of this year's assembly, spoke of his election in these words:

> "Has not this election upheld before the whole world the principle of equality as between large and small States, and demonstrated the spirit of true democracy? . . . up to the present, no-one from my part of the world had been honoured with this presidency; and so, in order that the principles

Medicine and the Law

Alleged Negligence in Injection

In a recent claim against a Glasgow doctor for £10,000 damages for his alleged negligence[1] the issue was perhaps unusually simple Mr James Reid attended the outpatient department of the Western Infirmary, Glasgow, for treatment for boils in the neck He was given, he said, an injection of penicillin on two successive days, the first time in the hip and the second in the right buttock As he was going home by tram after the second injection, he suddenly became aware of a complete loss of power and sensation in his right foot He was brought home with difficulty and suffered great pain for many hours the right leg had been helpless ever since, and amputation might be necessary His own doctor had come to the conclusion that at the second injection the syringe must have been thrust into the main sciatic nerve It was claimed that the injury, which would be *permanent*, was due to a negligent and reckless plunging of the needle into the nerve at a point fully six inches above the classical site for such an injection

For the defending doctor it was contended that, if the main nerve had been penetrated as suggested, the reaction of pain would have been immediate, had this occurred, the doctor would at once have investigated the cause of the pain, he had no recollection of any such occurrence Lord Blades, giving judgment in the Court of Session, said he had made up his mind without hesitation that he accepted the authoritative and convincing evidence, based on expert knowledge and wide experience of the very subject matter of the case, given by the two doctors called for the defence, in preference to the evidence given by the two doctors called for Mr Reid It was impossible for the court, upon that view of the evidence, to hold that Mr Reid had discharged the onus of proving his claim One might add, perhaps, that the defendant doctor must have been at some disadvantage in dealing with an allegation relating to treatment in an outpatient department six years ago

The Economics of Litigation

Another claim for damages based on charges of negligence has been brought to an end because, in the words of one of the Queen's Counsel engaged in the litigation, the profit would be almost exclusively to the lawyers In Basford *v* Board of Charing Cross Hospital and Others[2] the plaintiff's case was that in 1947, suffering from pain in his arm, he was treated for fibrositis at the Maida Vale Hospital for Nervous Diseases A year later he had headaches and worse pain and was sent to Wembley Hospital There the director of physiotherapy diagnosed a displaced spinal disc but took no X ray photographs Electrical treatment was given In 1949 a radiograph showed no evidence of a displaced disc, but the shoulder and arm were not photographed The patient received radiant heat and massage, went back to the Maida Vale Hospital, and was put down for radiography—but again, it was alleged, for the wrong place His employer then sent him to Sir Hugh Griffiths He was found to have a swelling as big as an orange on the upper arm and another on the shoulder, the growth had spontaneously fractured the bone Damages were claimed for the failure to make a sufficient examination of his condition at the proper time and to take X ray photographs, had the photographs been taken, it was contended, a malignant tumour or cancer would have been disclosed in the upper left arm and there would have been a reasonable chance of saving the limb The electrical treatment, radiant heat, and massage, it was said, were the worst possible treatment for a growing malignant tumour

Sir Hugh Griffiths stated his opinion that the growth would have been disclosed by radiography and, he thought, by palpation, definite diagnosis was difficult, the witness communicated with the Medical Research Council and the Atomic Research Council, a remarkable amount of investigation was carried out for this purpose After other evidence had been called and the case for the defendant director of physiotherapy had been opened, a settlement was announced on the third day of the trial Plaintiff's counsel said that proposals had been made which were satisfactory to his client and which provided for the plaintiff's costs In the circumstances he did not desire to pursue the allegations of negligence against any of the defendants Counsel for the latter agreed to the settlement while not admitting the allegations As four Q C s and four juniors were engaged on behalf of the various parties, the expense of an inevitably long hearing with much expert evidence, was an obvious deterrent The defendants, however, may well feel at a disadvantage inasmuch as the plaintiff's case was fully reported while their own had no chance of publicity

A Successful Action for Libel

Dr William Mervyn Crofton was awarded £2000 damages for libel in the action in which he complained of social justice might prevail, the great nations, which could easily have tilted the balance in whichever direction they chose, stood aside and renounced the presidency in favour of the small States.

---

[1] *Glasgow Herald*, May 2

[2] *Times* May 5–7

Dr. Brock Chisholm, the first director-general of the Organisation, who is retiring on July 21, presented his report for 1952,[1] which shows clearly how, during his tenure, the organisation has acquired stability and how it continues to meet international needs, which are becoming better defined.

Communicable diseases still present new problems, ever changing with the social and economic development of the people. Malaria control remains foremost, but in many parts of the world, notably in Asia, national governments are taking over and expanding schemes originally laid down and started by international consultants and teams. On the other hand, in tropical Africa malaria control is still in its early days and is attracting more and more attention. Tuberculosis comes second on the list of infectious diseases, and over 38 million young people have been tuberculin-tested and 18 million non-reactors vaccinated with B.C.G. The setting up of the international laboratory in Copenhagen for tuberculosis immunisation research is an important recent development. The international yaws campaigns seem to be steadily crushing the enemy and bear witness to the competent planning of the general staff behind them.

Education plays an increasing part in the work of W.H.O., and a total of 1147 fellowships were awarded in 1952. Of these, 487 were for group training; and W.H.O. organised 26 courses and assisted in 18 more, including those on Engineering Aspects of Public Health in London, Yaws Control in Bangkok, Anæsthetics in Copenhagen, Nursing Education in Taiwan, and Brucellosis in Santiago. Of the fellows, 666 were studying health organisation and services, 348 communicable diseases, and 131 clinical and medical sciences and education. In the organisation and execution of this programme, as in all W.H.O.'s work, there has been an increasing amount of decentralisation to the six regional offices. The regional office for Africa, directed by Dr. F. Daubenton, moved from Geneva to Brazzaville in October last and, despite recruiting difficulties, has begun a full programme in which the training of African doctors and medical auxiliaries plays a large part. The flourishing work of the South-East Asia regional office, under Dr. C. Mani, continues; here India seems to provide a model for the proper use of international aid and international experts. Much good work is also being done under very difficult circumstances in Burma, Indonesia, and Thailand.

The total assessments of the 71 member countries for the year totalled just under $9 million. The largest subscribers are the United States ($2·8 million), the United Kingdom (1·0), and France (0·5). Of the total subscriptions, 80% have already been paid, and most of the remainder is due from countries with Communist governments who continue to be "inactive members."

An important decision was taken at the Fifth World Health Assembly, when the increase and control of world population were discussed. There was considerable disagreement on the question of whether this was or was not properly a medical problem, and the assembly ultimately decided that no action should be taken. Many doctors in all countries must regret this decision, but clearly no international organisation can proceed without a substantial measure of agreement amongst its constituent members.

Any public-health report inevitably contains a large mass of factual data and details of organisation, which are not easy reading. The difficulty in presenting this work in an imaginative way is great, but W.H.O. has set an excellent example by including many fine photographs of its workers in the countryside, in hospitals, and in laboratories. These add immensely to the value of the report, especially for the non-technical reader.

After six years W.H.O. has a reliable and efficient secretariat, and an executive board which is capable of thinking internationally rather than nationally and which is thus capable of carrying out major international plans. These achievements are in no small measure due to Dr. Brock Chisholm's vision and energy.

EARLY SURGERY IN SKELETAL TUBERCULOSIS

It happens not uncommonly that an important advance in surgery, though long foreseen, depends for fruition on developments in another field of science. The internal fixation of fractures by metal—an idea that had been cherished since the early days of aseptic surgery—had to await the development of biologically inert metals. A parallel situation is seemingly evolving in the early surgical treatment of skeletal tuberculosis; in this case the accessory is the development of effective antibiotic drugs.

Long before the introduction of antibiotics the idea of a direct surgical attack on a tuberculous focus in bone or joint had seemed theoretically attractive to orthopædic surgeons, and such operations were occasionally practised. But the results were often discouraging: dissemination of the disease to other organs and the formation of chronic discharging sinuses with secondary infection were common sequels. Consequently the attitude of most surgeons towards skeletal tuberculosis became strictly conservative, especially in Britain. Operative treatment was seldom undertaken except in the quiescent phase of the disease, and even then the surgeon sought to avoid cutting directly into diseased tissue. The introduction of antibiotic drugs—especially streptomycin—has led to reconsideration of the possible advantages of a bolder policy. Many surgeons now believe that, with the greater security against unfavourable complications afforded by streptomycin, direct operation on tuberculous lesions of the skeleton may prove, after all, to be advantageous. Johnson et al.[1] suggest that certain lesions can be tackled surgically with impunity and probably with benefit to the patient; and Wilkinson[2] makes it clear that similar observations are being made in Britain. In following up this development orthopædic surgeons must beware lest their enthusiasm carry them too far. A proper note of caution was struck in the British Orthopædic Association's discussion of Pott's paraplegia, summarised on p. 799. Whatever its local manifestations tuberculosis is a systemic disease. Therefore constitutional treatment must continue to be the first method of attack: to advocate surgical treatment without proper constitutional measures is to court disaster.

Johnson and his collaborators emphasise the value of operation in diagnosis. Important though this may be, it is mainly in the hope of hastening the healing of the lesion that British surgeons are investigating the possibilities of surgery. So far, early operation has been undertaken mainly for the thorough evacuation of abscesses and the removal of tuberculous debris by curettage, especially in spinal disease. Synovectomy is also under trial in selected joint lesions. Such operations should create favourable conditions for rapid healing; and in spinal disease drainage of paravertebral abscesses will help to prevent extension of the infection along the of language used in the report of a tuberculosis conference which he had attended at Hackney in June, 1950 The report after describing claims he made at the meeting for the success of his own method of treatment and the statements of his supporters "including several patients whom he had brought with him to demonstrate so-called 'cures'" went on to say that "the conference, however, soon recognised the language of the quack remedy advertisements and passed on to discuss tuberculosis problems in East London" Dr Crofton complained that these words meant that he had falsely claimed to have effected cures, was not fit to be on the Medical Register, was advertising himself in an unprofessional manner, was a pedlar for his own profit of cures which he knew to be valueless, and had conspired with others to deceive the public The defendant denied those implications, but admitted that the words could mean that the plaintiff was advertising himself unprofessionally, in that sense said the defendant, the words were true in substance and in fact in so far as they were matters of opinion they were fair comment without malice on a matter of public interest The jury found that the words were defamatory that they were not true in substance and in fact, and that they meant that Dr Crofton was a charlatan, not fit to be on the Register, dishonest in falsely claiming to have effected cures advertising himself in an unprofessional manner and peddling a method of cure which he knew to be valueless, for his own profit In further answers to the judge's questions the jury said that if the words meant only that the plaintiff was advertising himself in an unprofessional manner, they were untrue, that they were not fair comment and that the defendant was actuated by malice in publishing them

[2] Wilkinson, M. C. See *Ibid*, 35B, 150.

Dr Crofton, in the witness-box, explained that his method was to take a culture from tuberculous patients' sputum and so produce immunisation There was no secret about it, he had publicised it as much as he could After his attention had been drawn to the report, and its author had been identified, he received a private letter of apology, but, three days later, the defendant had put on record in the present action his plea that the words were true and that he meant them to imply advertisement in an unprofessional manner Mr Justice Finnemore, in his summing up to the jury distinguished between a doctor saying "Come to me and I will cure you" and saying "Here is a method which any doctor can use and which, if used, will eliminate tuberculosis"

The law of libel in England is a remarkably flexible instrument for deciding a dispute If the judge and jury in Dr Crofton's case were not exactly performing the function of the Medical Research Council or the Ministry of Health in assessing the merits of his system of treatment, they were in some degree deputising for the General Medical Council in passing judgment on his professional conduct

Parliament

Priority for the Mental Health Services

REPLYING to a debate on the adjournment in the House of Commons on May 7, Miss PATRICIA HORNSBY-SMITH said that the number of inpatients who were mental defectives at the end of 1952 had risen to 53,066 as against 51,194 in 1951 But there was still a growing waiting-list, and a large proportion—about 4000 out of 8714—were children These children were mostly in the age-group 4–7 when it was difficult to keep them at home But progress in staffing beds had been made At the beginning of January 1952, there were 2145 unstaffed beds in mental-deficiency institutions At the beginning of 1953 there were 1587 unstaffed beds The first problem was more nurses and the second more buildings

The Minister of Health had repeatedly said that priority must be given to the mental side in capital expenditure In the Leeds area for example, in the two-year programme, out of an expenditure of £190,000 the sum of £102,000 was going to mental deficiency and in East Anglia £49,000 was being allocated out of £181,000 for the 1953–54 programme The largest project on hand was Greaves Hall, near Southport, which would cost £3 million, take five years to complete and provide 1040 beds In the last two financial years £899 000 had been spent on improvements in the purchase of buildings and adaptations for mental-deficiency work.

The staff in 1948 were 6000 full-time and 50,000 part-time and at the end of 1952 the figures were 6610 full-time and 54,665 part-time, but she agreed that they still needed many more

QUESTION TIME

Accommodation for Mental Defectives

Mr B R BRAINE asked the Minister of Health if he would give the figures of recognised bed space set aside for mental defectives in England and Wales and the number of beds not used for lack of staff or other reasons—Mr IAIN MACLEOD replied On Dec. 31 last, including certified institutions and approved homes outside the National Health Service, the bed figures were as follows recognised bed space, 50,401 out of use, 1921, occupied, 53,914

Mental-deficiency Nurses

Mr BRAINE asked the Minister what steps had been taken on the advice of the Mental Health Advisory Committee and others to recruit additional staff for mental-deficiency nursing—Miss M. P HORNSBY-SMITH replied The Standing Mental Health and Nursing Advisory Committees have not yet completed their study of the problem, but they have tendered interim advice to the Minister of Health in the light of which he hopes to issue a memorandum of guidance to the management committees concerned in the course of the next few weeks. He is also considering, with the Minister of Labour, the desirability of devoting the resources available for recruitment publicity in the current financial year largely to the recruitment of mental, and mental deficiency nurses

National Health Service Cost

Major TUFTON BEAMISH asked the Minister of Health what extra cost would fall on the Exchequer in this financial year if the National Health Service were made free in all respects—Mr MACLEOD replied. It is, of course, difficult to estimate the level of demand that would result if charges were removed, and therefore no accurate estimate is possible; but I think that the extra cost in a full year would be at least £40 million.

Committee on N.H S Costs

Mr SOMERVILLE HASTINGS asked the Minister what knowledge and experience of the work and management of hospitals was possessed by the members of the committee that was to inquire into the cost of the health service—Mr MACLEOD replied The inquiry is to be independent and objective, the members appointed have, therefore, no direct connection with any part of the health service The committee will decide their own procedure, but I have no doubt they will wish to take evidence from organisations and individuals with knowledge and experience of the working of the service

Mr HASTINGS Does not the Minister feel that some knowledge of the work of a hospital is necessary for those whose job it is to assess the value of what is spent on that hospital?—Mr MACLEOD Frankly, I disagree If we once start having representatives of hospitals, in any sense of the term, I should have to have representatives of doctors consultants, dentists local authorities, opticians, and the rest I wanted this problem to be examined by a committee of five wise men, or four wise men and one wise woman—whatever we like to call it I think we shall get the best result from that

Mr ARTHUR BLENKINSOP Could the Minister say why he has by-passed the central advisory committee, which is there surely to give him advice on this and other matters?—Mr MACLEOD For the very reason I have just explained, because the Central Health Services Council is representative of all the interests in the health service For that reason, in my view, it is the wrong body for this kind of inquiry.

Junior Hospital House-officers

DR BARNETT STROSS asked the Minister whether he was aware of the difficulty experienced by some hospitals in spinal column. It is not yet known whether the beneficial effects of operation are due solely to efficient drainage of pus and debris or also to some other mechanism; some believe that the mechanical disturbance of tuberculous tissue in some way stimulates the resistance of the body to the disease. More will certainly be heard in coming months of the surgical treatment of skeletal tuberculosis.

THE LIND BICENTENARY

IN 1753 the naval surgeon, James Lind, a graduate of medicine of Edinburgh University and a native of the town, published his *Treatise of the Scurvy*. This weekend in Edinburgh, Town and Gown combine with the Royal College of Physicians and the Nutrition Society to celebrate the bicentenary. Visitors from the U.S.A., France, Belgium, and Holland have come to attend the official receptions, to take part in four symposia on modern aspects of vitamin C and scurvy, and to listen to a Lind oration from Surgeon Vice-Admiral Sir Sheldon Dudley, F.R.S. The Edinburgh University Press has reprinted the original first edition of the treatise, together with additional notes on Lind and his contemporaries and on the chemistry and physiology of vitamin C.[1]

The modern reader will soon find that this reprinting is more than a proper act of filial *pietas*. The layout of this 200-year-old monograph is essentially modern and includes chapters on epidemiology, diagnosis, prognosis, prophylaxis, and treatment, together with a discussion of the history of the disease and a good bibliography. The book is written in elegant English, characteristic of the great age of Edinburgh literature which was just about to begin. There is little of the topical professional jargon, which mars so many medical books in all ages.

The clinical description of scurvy remains, without doubt, the best available to the student. Lind, like many of his generation of naval surgeons, had a clinical experience of thousands of cases, and certainly no modern physician can write with such personal authority. His clinical trial of oranges and lemons, together with other remedies of repute at the time, was carried out at sea in H.M.S. *Salisbury* in May, 1747. Today it is still a model of how to plan and conduct a therapeutic trial. This experiment established beyond any doubt that these fruits, alone out of many recommended remedies, were capable of curing the disease. Lind was also well aware that a supply of fresh fruits and vegetables was of fundamental importance in the prevention of the disease during long sea voyages. But modern nutritionists will be interested to find that he thought that the stresses and strains of the life of the sailor, and especially the repeated exposures to damage and cold, played an important contributory part in the onset of the symptoms of scurvy.

Five years after the publication of the treatise Lind was appointed chief physician to the new R.N. hospital—Haslar Hospital, at Portsmouth. At the time this was probably the largest hospital in Europe and could receive 2200 patients. In his first two years of office 1146 cases of scurvy were admitted. Lind held this post for twenty-five years; yet such are the delays in the introduction of new knowledge that he did not live to see scurvy eradicated from the Navy. James Cook was indeed able to complete his second great voyage to Australia in 1772–75 without a single case, but not until 1795, a year after Lind's death, did the Lords of the Admiralty supply lemon juice to the sailors at public expense, "which acted so speedily that in less than two years it became extinct." A miracle in the preservation of sailors was thus effected. Sir Gilbert Blane, a pupil of Lind, was largely instrumental in bringing the Sea Lords to this decision. The additional notes to the reprint include an account by Dudley of the Lind tradition in the Royal Naval Medical Service. Largely through his pupils, the aristocratic Blane and Thomas Trotter, who like Lind had started as a surgeon's mate, he was able to secure immense improvements in the conditions of life at sea. After the introduction of lemon juice Blane wrote: "One of the most distinguished sea officers that ever lived declared to me that it was his conviction that two ships are now equal to four of former times." Dudley adds that a man who could double the striking force of the King's Navy with no increase in the "naval estimates" or use of that dread instrument the press-gang was worth half a dozen ordinary admirals. In fact Lind's influence effected much more than the prevention of scurvy and extended far beyond the Navy. In directing his naval medical colleagues towards attempts to preserve the health of the seamen in addition to their regular duties of treating their diseases, Lind was a pioneer of modern public health and social medicine.

The editors have carried out their work unobtrusively, and the beautiful printing is a credit to modern Edinburgh craftsmen. Those who read this book will find a fascinating mixture of medical science and naval history.

---

[1] Lind's Treatise on Scurvy: A bicentenary volume containing a reprint of the first edition of *A Treatise of the Scurvy* by JAMES LIND, M.D., with additional notes. Edited by C. P. STEWART, PH.D., D.SC., and DOUGLAS GUTHRIE, M.D., F.R.C.S.E. Edinburgh: University Press. 1953. Pp. 440. 45s.

PHÆOCHROMOCYTOMA

FOR a long time phæochromocytoma was largely a post-mortem diagnosis, but now there are methods of investigation which afford a greater opportunity for early recognition of the tumour. Adrenolytic drugs such as benzodioxane ('Piperoxane')[1] and phentolamine ('Rogitine')[2] are amongst the useful diagnostic tools, although both may give misleading results. And, as Dr. Cobb and his colleagues report on an earlier page of this issue, benzodioxane can also be used to control the rise in blood-pressure during an operation on a phæochromocytoma; and phentolamine can be used for the same purpose. In diagnosis, provocative drugs such as histamine,[3] methacholine ('Mecholyl')[4] and tetraethylammonium bromide[5] may precipitate severe hypertensive attacks and are probably better avoided. A still more direct investigation is the measurement of the urinary excretion of catechol amines,[6] the results of which have proved almost uniformly reliable. This assay, however, is at present performed in only a few centres, so that it is well to consider how far it is possible to diagnose phæochromocytoma using simpler tests. Smithwick and his colleagues[7] collected detailed information on the many patients referred to them for splanchnicectomy for hypertension. Amongst these patients there were 11 with phæochromocytoma, in most of whom the tumour was not diagnosed before operation. A subsequent analysis of all the clinical data of these 11 cases, together with those of 107 reported cases and of 100 unselected cases of essential hypertension, showed a number of differences which served to identify those of phæochromocytoma. A high proportion of the patients with phæochromocytoma gave a history of excessive sweating or vasomotor disturbances, such as coldness or blanching of the extremities. At least 70% of them, as against 10% of those with essential hypertension, had unexplained rises in body-temperature of 1°F or more; and in over 60% the basal metabolic-rate

obtaining candidates for junior house positions, what was the extent of this problem, and whether he would consider increasing the payment for locums for these positions from the present rate of £8 per week.—Mr MACLEOD replied: I am aware that this problem is widespread, particularly in the remoter hospitals. I am considering how it can be solved, but I do not think a solution can be found on the lines suggested.

Dr STROSS: Does the Minister recall that I wrote to him about a hospital which is not remote and which has 1000 beds in Stoke-on-Trent where I think that four out of the five surgeons have no assistance? Does he not think that increasing the remuneration above £8 per week might help them to get locums?—Mr MACLEOD: One of the difficulties about the scale was that it was only promulgated in November, 1952. The second difficulty seems to me to be that to encourage people to take locum jobs is not right from the long-term point of view. The best solution may well be secured by seeing what happens as a result of the preregistration Act which has come in this year.

Specialists and Merit Awards

Dr JEGER asked the Minister how many merit awards had been made each year since the system was instituted.—Mr MACLEOD replied: 1740 awards were made in England and Wales for 1948–49, 439 new or higher ones for 1950, and 229 for 1951. Recommendations have not yet been received for 1952.

Mr BLENKINSOP asked the Minister the total number of full-time specialists now employed in the N.H.S., as compared with the number twelve months ago.—Mr MACLEOD replied: There were 2149 whole-time consultants and senior hospital medical and dental officers at the end of 1950 and 2445 a year later.—Mr BLENKINSOP: This will give some satisfaction because of the rather anxious reports which have been put out by many full-time consultants that there has been a great falling away of that service. But, nevertheless, it is very much more costly to encourage recruiting of part-time specialists than to encourage further full-time appointments.—Mr MACLEOD: Those figures only take us up to a little more than a year ago. I have not the 1952 figures—which will be interesting—but I hope to have them by about the end of the month.

Atmospheric Pollution

On the motion for the adjournment in the House of Commons on May 8 Mr A. E. MARPLES, parliamentary secretary to the Ministry of Housing and Local Government, stated that the Government had decided to appoint a committee under an independent chairman to undertake a comprehensive review of the causes and effects of air pollution and to consider what further preventive measures were practicable.

Public Health

Smallpox

A FURTHER 3 cases of smallpox have been reported from Yorkshire, bringing the total of confirmed cases in the outbreak to 30, with 7 deaths. The daughter and son of the Leeds mortuary attendant who was admitted to hospital on May 2 are now known to have smallpox. The girl, who was vaccinated for the first time on May 2, fell ill on May 6, and the boy, who had his primary vaccination at the same time, on May 10. The third new case is that of a miner, aged 19, who lives at Baildon and works in a colliery at Gomersall. He was not under surveillance as a contact, but he lives 3 or 4 miles from one of the earlier patients. He fell ill on May 1 and was admitted to hospital on May 5.

Death from smallpox may take place in the pre-eruptive stage or when there are only sparse focal rashes. The patient may be desperately ill—perhaps comatose—on reaching hospital, and in the absence of any rash his condition may easily be attributed to some other acute medical or surgical illness, such as uræmia or an abdominal condition requiring laparotomy. A patient who has been very ill in the early stages of smallpox does not necessarily develop a definite rash later. Thus smallpox enters into the differential diagnosis of any unexplained fever and toxæmia, particularly with hæmorrhage or petechiæ. When there is the slightest doubt material should be kept for virological examination, and the medical officer of health notified.

In England Now

A Running Commentary by Peripatetic Correspondents

I RAN the Pathologist to earth in a rather small dirty room. He was smoking a cigarette, his glasses were pushed up on his forehead, and he didn't seem too busy. "Can you tell me, sir, please," I asked, "why differential white-cell counts are always given as percentages of the total whites? ... I mean, the different white cells don't bear any particular relation to each other, do they, sir?" He appeared to be trying to take this in, so I was encouraged to make it a bit simpler. "Supposing you enumerated all the different objects in a living-room for instance," I said, "within normal limits you might expect one grand piano, half a dozen chairs, two or three tables, a few rugs, curtains, vases, pictures, and, say, a couple of hundred books. Your percentage of grand pianos would average about 0·3% and would depend largely upon the number of books. It might be as low as 0·15% in a library or as high as 2% in a studio. Right? Very well, but supposing there were *two* grand pianos in the room, sir—" He took me up promptly. "There are people who would need two. Rawicz, for instance. And Landauer, too, I wouldn't mind betting." "So that they could visit each other, turn and turn about?" I hazarded. "And Sellick and Smith?" "Oh, but they are married, aren't they, sir?" He nodded sagely, and went on with enthusiasm. "And there's that thing of Bach's that old H. J. was so fond of at the Proms that takes *three* grand pianos. He used to give it to his students. My niece played in the team one year, I remember. Outside right, I think she was." "Really, sir? Then I may have seen her." I persevered, "But my point is that more than one grand piano in a room has a definite significance. Half a dozen would be pathological." He agreed, "Half a dozen would be excessive. ... Didn't they have four in *Les Noces*, up on the stage?"—"No, two I think. Four voices, or was it eight, but only two pianos. But lots of percussion." He nodded happily, "Yes, lots of percussion." I ploughed on, "Well, people can have from one to three grand pianos in the room and still keep within the normal percentage range, so long as there are enough books and vases and things to balance them up, or do I mean dilute them?" "I can't see anything wrong in that," he replied after deliberation. "Good," I said. "Now, sir, some of your white cells—I can't remember their names—are as scarce as grand pianos, and their actual number can be doubled and trebled without anyone paying much attention if their number is expressed merely as percentages of the white-cell count. In fact, I'm surprised you don't lump in the reds as well and divide the number of thingummy cells by five million odd. ..." "I dare say we could do that for you. It would only mean dividing by five and shifting the decimal point. Would that help you?" "No, no, sir," I exclaimed hastily. "Not a bit. Quite the contrary in fact. I'd like you to divide each cell quantity by its own particular normal so that your path. report would read—Polys normal, Lymphos two-thirds normal, Thingummy cells five times normal." There was a pause and then the telephone rang. With heavy deliberation he took up the receiver and listened. With his right hand he drew on his blotter an Aberdeen terrier balancing a sugar-lump on its nose, putting in the shading very carefully. A laboratory assistant barged in, noisily dumped a basket of test-tubes on the desk, looked at me pityingly (I thought), and barged out again. The telephone earpiece cackled and burred. "All right," said the Pathologist, "I'll hang on," and went on with the shading. I crept out.

* * *

The remarks of your non-psychiatric, but without doubt psychologically eminent, peripatetic correspondent (April 4) who has designed a de-luxe body for his 10 h.p. car reminds me of an awkward situation which I successfully overcame in my youth (1939). I had an ancient 1926 Austin Seven of which I was inordinately proud. It was, however, always embarrassing, especially when there were young ladies aboard, to hear a stream of scurrilous and derisory remarks whenever I stopped at a garage. There was one garage hand, a large, lanky, ginger-haired coarse youth, whom I particularly disliked,

a) *Not Frigid.*—Although not frigid by definition, these 6 tients had all experienced coitus far in excess of their sires or their capacity to attain orgasm.

(*b*) *Frigid Throughout Marriage.*—This, the largest group, mprised 162 women. A history of undue mother attachment s given by 83% while 23% developed gall-stones.

(*c*) *Frigid After Marriage.*—There were 128 in this section. itus, which had been completely or partially gratifying ring the early years of marriage, ceased to be desirable satisfying at a later period, usually in conjunction with a owing family (case 3 is a typical example). The percentage gure of 14 with mother attachment at marriage approximates that of the general community. Gall-stones occurred in 2·5%.

LASSIFICATION OF 300 PATIENTS WHOSE CHIEF COMPLAINT WAS FLATULENT DYSPEPSIA

Cases	Frigidity	Total	Mother-attached	Gall-stones
Married women	Not frigid	6	0	3
	Frigid throughout marriage	162	135	37
	Frigidity acquired after marriage	128	18	16
Single women		3	3	1
Male		1	—	1

4. The findings among single women, and the proportion exhibiting mother-attachment in group 3(*b*) (namely 83%), lead to the inference that not only does an undue attachment to the mother predispose to flatulent dyspepsia but in accentuating the maternal component of womanhood it interferes with erotic growth and thereby contributes to female frigidity. The development of maternal qualities through the rearing of a family seems to have a similar effect.

My own conclusion from these 300 cases and from many hundreds of milder cases and of various control groups is that in general the severity of the disorder is in direct proportion to the frequency of unappreciated coitus.

MECHANISM

In speculating on why the revolt against unwanted coitus should express itself in apparently remote symptoms, several factors need consideration.

The Conditioned Reflex.—Pavlov showed that a stimulus, as it travels from sense receptor to end-organ, leaves in its wake a change of some permanence in the cerebral hemispheres. The response to further similar stimuli is intensified or widened in scope by the summation of past stimuli, so that a conditioning may reveal itself as a profound response to a comparatively slight stimulus. Of the many emotions evoked by the physical act of submission to an unloved husband, disgust, fear, anger, and displeasure are most readily recognisable in the sequelæ of flatulent dyspepsia, nervousness, hypertension, and rheumatism. Women conditioned by this ordeal may yet enjoy a remarkable state of well-being during a respite in hospital or at a holiday resort; but rapidly relapse in the environs of their homes and husbands.

Endocrine.—The decisive influence of parental associations in early life on personality structure and character formation are well known but their effects on female hormonal activity are still largely uncoördinated. From observations made in our practice the following generalisations seem to be emerging:

When the growing girl enjoys much of her father's company and forms a strong affection for him (especially if the mother's influence is small), the menses tend to appear early. The girl shows a vivacious temperament and an urge to mix socially with the male sex in adolescence. Sexual difficulties in marriage are rare. Nausea, vomiting, and varicose veins are absent or very slight, at any rate in early pregnancies.

When the father is indifferent, strict, harsh, or drunken, there is an average relative delay of two to three years in the onset of menstruation. The girl adheres to the mother, assisting her in the home, is bashful and diffident in mixed company, and has a low male acceptance, often amounting to complete sexual frigidity on marriage.

On this basis the influence of the father during childhood and adolescence is towards promoting erotic growth and acquiescence in pleasurable sensations, whilst that of the mother is towards promoting motherliness and a stoical acceptance of work. These rôles are antagonistic but complementary and find their counterpart in the sequence of mating and pregnancy and also in the follicular and luteal phases of ovarian function. Indeed, if the clinical observations are correlated with the endocrinological data, the following broad classification emerges:

(*a*) The strongly erotic female has relatively high œstrogen levels and usually menstruates early, vigorously, and regularly. She often suffers from dysmenorrhœa and may have an inadequate milk secretion after parturition.

(*b*) A strong motherly component coupled with a weak or inhibited eroticism results in a relative preponderance of progesterone-relaxin values. Menstruation appears at a later average age and is unattended by dysmenorrhœa. Subject to the appropriate conditions in later life, there are found in this group temporary amenorrhœa, anorexia nervosa, nausea, vomiting, and varicose veins in pregnancy, adequate lactation after parturition, premenstrual tension, visceroptosis, uterine prolapse, herniation at operation scars, flatulent dyspepsia, and gall-stones.

Gastrohepatic Function.—Though the association between disgust and vomiting is common knowledge, the precise consequences of this emotion on stomach and liver function are still largely undetermined. Women who suffer from flatulent dyspepsia have a low fat-tolerance, are immune from peptic ulceration, and are inclined to be hypochlorhydric and to develop gall-stones.

HUSBANDS AND WIVES

The assertion that love, while playing but a part in the life of man, is woman's whole existence, is one of these misleading half-truths; for, whereas the erotic requirements of the female are intermittent and transitory, the male is enslaved by his need of female affection throughout his span of life. On finding in marriage the futile pretence, passivity, or protest in lieu of subtle caress and passionate embrace, he is by no means unhurt; but the emotions engendered by this threat to his security are of a very different nature from those of his frigid wife.

The husbands of the greater part of this series of 296 married women were still alive during investigation, and a number were known to me. Unfortunately, my attention was not drawn to them until 1944 when many of the patients had drifted beyond my reach. The data obtained from just over two-fifths of them indicate their more typical reactions. Roughly, 25% became addicted to alcohol and 20% contracted peptic ulcer, while an unknown but substantial proportion found solace in the arms of other women. Many compensated through vocational diligence in gaining positions of influence and responsibility in the community.

The process of growing up involves a transition in habitude from the all-play to the purposive; but even the lives of the fully mature require a leavening of joy to maintain health.

Clinical experience teaches that a grossly overworked housewife will eventually show minor or major rheumatic manifestations. These will come into being the sooner if the fundamental pleasure principle normally associated with marriage is substituted by other emotions. When her reaction to a drunken husband is dominantly one of anger and hostility, hypertension looms ahead, probably via a sympathetico-renal mechanism. If sexual disgust has played a substantial part in her life, the result will be the gastrohepatic disorder here called rejection dyspepsia.

Whether in detail I am right or wrong in these interpretations, I am certain at least the habits, the emotions, the endocrine imbalance, the bodily changes and social repercussions of the mass of sexually maladjusted women constitute a challenge of the first magnitude to the doctor of today At present their endless complaints are usually dealt with mechanistically Drugs are administered to counter their states of mind, to balance their endocrines, and to interfere in the function of their bodily parts When structural changes are deemed irreversible, operation follows The poor reward attending these therapeutic efforts can readily be traced to the continuance of the noxious emotional factors in their lives and to the difficulty in destroying a conditioned reflex once established

SUMMARY

A syndrome entitled "rejection dyspepsia" is described Among the commonest complaints met with in adult life, it is largely confined to married women and probably has the same origin as the nausea and vomiting of pregnancy and gall bladder disorders Predisposition depends on factors in early life, notably lack of affection for the father and over attachment to the mother with consequent erotic inhibition and female frigidity Precipitating factors include a continuance of association with the mother, marital incompatibility, a rapid succession of pregnancies, and the frequency of ungratifying coitus

I am deeply indebted to my partners, Dr G Ronald Anderson, Dr Gordon J Ker, and Dr Norman D Ker, for their help in the assessment of clinical data, to Dr I Anderson and the biochemical staff of the Victoria Infirmary Glasgow for carrying out many urinary pregnanediol assays in women who had had varicose veins in pregnancy, and to Dr Ranyard West and Dr Peter L McKinlay for helpful criticism in the preparation of this paper

URINARY EXCRETION OF PEPSINOGEN IN GASTRODUODENAL ULCERATION

B I HIRSCHOWITZ[*]
B Sc , M B Witwatersrand, M R C P E , M R C P
MEDICAL REGISTRAR, CENTRAL MIDDLESEX HOSPITAL, LONDON

THE existence of a pepsin-like enzyme in the urine has been known for more than ninety years (Brücke 1861) Despite the discovery of the inactive pro enzyme of pepsin, pepsinogen (Langley 1881), it was thought that this urinary enzyme was free pepsin, and Benderskoy (1890) called it uropepsin Evidence which has accumulated since then has shown that this urinary enzyme is free pepsinogen Final proof of its identity came from the experiments of I A Mirsky et al (1948) in which intravenous injections of pure pepsinogen increased the urinary excretion of enzyme, whereas pepsin, either injected or given by mouth did not do so The term "uropepsin" is therefore incorrect and should give way to the more precise term "urinary pepsinogen"

The enzyme originates in the peptic cells of the stomach (Langley 1881) The persistence of pepsinogen in the leucocytes sometimes for years, after total gastrectomy indicates that these cells probably elaborate some pepsinogen endogenously, but this accounts for very little of the urinary enzyme

The relation between the level of urinary pepsinogen and gastric secretory activity is uncertain Varró et al (1952) deny any such relationship, but Gottlieb (1924) and Janowitz and Hollander (1951) claim that there is a close relationship The evidence presented by the latter workers is the more convincing

Pepsinogen diffuses into the blood directly from t stomach wall, none being reabsorbed from the g lumen (Mirsky et al 1948) The enzyme is filter through the *renal glomerular membrane* and part reabsorbed in the tubules, as will be shown in a pap to be published elsewhere

Before X-ray diagnosis of gastroduodenal disea came into general use, the diagnosis of carcinoma o the stomach was sometimes based on the estimation o urinary pepsinogen, but for this purpose the test valueless (Rothschild 1930) By the time radiograph diagnosis became general, about 1930, work on urinar pepsinogen had been dropped

Since the introduction of the more reliable and accurat hæmoglobin method of peptic assay by Anson and A E Mirsky (1932), and its application to urinary peptic assay by Bucher (1947), the investigation has been applied in cases of gastric and duodenal ulcer by Podor et al (1948) and by Janowitz et al (1950), who have tried to show a difference in urinary excretion of pepsinogen *between normal people and those with peptic ulcer*

I describe here the disturbances of urinary excretio of pepsinogen in patients with gastric and duodena ulcers

TABLE I—AGE DISTRIBUTION AND MEAN URINARY PEPSINOGE IN CONTROLS

—	Sex	Age group (yr)					Tota
		15–29	30–39	40–49	50–59	60 or more	
No of persons	M	7	6	7	8	8	36
	F	2	5	8	4	5	24
Total		9	11	15	12	13	60
							Mea
Mean urinary excretion of pepsinogen ([P U]^{Hb} per hr)	M	216	277	183	103	205	19
	F	160	213	243	267	236	21
Mean		248	246	215	157	217	215

METHODS

The hæmoglobin method of peptic assay modified from Anson and Mirsky (1932) was used

Dilute a 10 ml aliquot of a timed measured output o urine (a twelve hour or a twenty-four hour sample) to 12 5 ml with 0 33 *N* hydrochloric acid Of this incubate 1 ml (≡ 0 8 ml of urine) for ten minutes at 37°C with 5 ml o acidified 2% hæmoglobin substrate (≡ 0 1 g of hæmoglobin) † Add 10 ml of 0 3 M trichloracetic acid and filter A parall blank estimation is made, the urine being added to the tri chloracetic acid to inactivate the enzyme before the sub strate is added The filtrate of each is dealt with similarly— i e , to 2 0 ml of filtrate add 1 2 ml of 1 3 diluted Folin Ciocalteau reagent, and then add 4 ml of 0 5 *N* sodium hydroxide and shake immediately A blue colour develops which is most *intense between five and twenty minute* The colour is measured in a spectrophotometer at 560 mμ, and the difference between the blank and the incubated specimen is compared with the colour produced by a standard aqueous solution of 1 tyrosine containing 2×10^{-4} m eq in 2 0 ml

1 unit is that amount of enzyme which will release the spectrophotometric equivalent of 1×10^{-4} m eq of 1 tyrosine from 0 1 g of hæmoglobin substrate in a ten-minute digestion at 37°C (modified from Janowitz et al 1950) The results are all expressed as units per hour, which is a more reliable index of urinary excretion in the individual than concentration (Gottlieb 1924 Bucher 1947, Mirsky et al 1948), and for each patient in this report represents the average of two or more specimens of urine To conform to the standard usage

---

[*] In receipt of a Medical Research Council grant

† Armour's bovine hæmoglobin enzyme substrate powder was mad up as a 2% solution in 0 15 N hydrochloric acid (Anson 193) *This acts as a buffer of moderate strength the pH of the incubate then varying only from 1 8 to 2 1*

and there was one young lady whom I especially wished to impress, and I laid my plans carefully.

With my young lady aboard I stopped at the garage; the lanky ginger youth came forward his nose in the air, and would no doubt have made some rude comment had I not forestalled him with a peremptory command to fill her up (1½ gall.). He bent down, unhitched the decrepit bonnet and threw it up. His mouth fell open, his eyes popped out, and he jumped to his job with a promptness and civility I had never before experienced. With aluminium paint even an ancient Austin Seven engine can be made to look like one of the shining gleaming aero-engines we sometimes see on display during the Battle of Britain week.

* * *

I sat with my hand immersed in hot wax and looked round for entertainment. The physiotherapy department is a small building separate from the main hospital, and this morning it was nearly empty. "My" therapist, who sometimes has time to chat, had completed her duties—namely, handing me a clean towel on arrival—and disappeared to another patient at the far end of the corridor; a young boxer brooded alone over his biceps in another cubicle. My mind began to occupy itself with a door across the passage marked OCCUPATIONAL THERAPY, apparently always locked and never seen to admit or let out anyone. So when Sister rustled along to smile at me, I seized the opportunity to ask when the room was used. I hoped to be shown (when disentangled from the wax) a room full of busy patients integrating their egos with raffia or sublimating with poster paints. "They come to dinner," said Sister surprisingly. "How odd," I remarked. "Yes, it *is* odd," replied Sister thoughtfully. "They come every day to dinner. I suppose they like the food better here than at the other places." I mused a little. "Of course," I observed, "eating is an occupation and it is often therapeutic, but to come here. . . ." "I think it peculiar myself," said Sister dryly and rather disapprovingly. "They have their meals and then get into their cars and go." "Where do they go?" I inquired fascinated. But instead of saying "Home," she mentioned the names of places here and there in the county, mostly unknown to me. It seemed odder still until the word "cars" returned to me and light dawned. "Do you mean the Occupational Therapists?" I asked. "Yes," replied Sister; "they all come here for meals." "But the patients," I faltered; "when do they come?" "Oh, the patients!" Sister dismissed them disdainfully. "I don't know when *they* come. I really don't know anything about them" she added after some thought, and rustled away.

* * *

When first we met, about three weeks ago, he had just killed a blackbird in my garden, and I was much upset. Perhaps that is why my aim was so good: he got a wallop on the back of his head that stunned him. I was completely unnerved, having missed every target since boyhood and having no intention of hurting a living thing. "Poor puss," I muttered as I stroked him back to normality, "you're just a cat."

Whether or not it was my best bedside manner I cannot say, but I haven't been able to get rid of Archibald since. No-one has answered my expensive advertisements about his having been found, and the local R.S.P.C.A. man tells me that the only home he might find for him would be a "long" one. Archibald, in other words, has adopted me, just as I, somewhat against my judgment, have adopted him. I comfort myself with the reflection that in a mixed practice one can't have everything. There are patients and patients. The birds are my first love, my old established friends who have learned to trust me. I am not sure what they think, but Archibald, rapscallion that he is, is now on my list and shows no wish to transfer to another doctor. For my own peace of mind, I am putting a nice wire-netting fence round the birds' pond and giving them a more elaborate feeding-tray. I only hope that Archibald appreciates my difficulties.

News from Hospital.—Our geriatrist has recently been warded with a virus pneumonia. After a few days we were relieved to read the report of our Jamaican night nurse that "Doctor complains of feeling all right today."

Letters to the Editor

HOSPITAL COSTING

SIR,—I was surprised at two examples "Administrator" gave last week to make his point that large-scale extravagancies exist within the hospital service: he instances that losses of bed-linen included sums of £6963 and £8150 at two large hospitals, and that farms and gardens run by hospitals showed a national deficiency of £614,033. There appear to be important fallacies in relation to such losses of linen; for it seems that, in stocktaking, ward deficiencies are taken into account, but not any excesses. When complete stocktaking of the entire hospital is taken on a single day, it has been found that apparent discrepancies may largely melt away. It does appear that the stocktaking system in hospitals needs overhauling.

It is entirely unfair to consider the cost of gardens in this context. In my opinion hospital gardens should be rated in the same category as hospital catering. They are essential for the well-being of the patient; some contact with trees, flowers, and lawns makes a very real therapeutic contribution, particularly for those who have to stay in hospital more than a few days. A distinguished American whom I was showing round a hospital commented that in his country they could not afford such gardens. He may have been a keen hospital economist, but I think his remark revealed a pathetic lack of any knowledge of the psychology of the average patient, at least in this country. With regard to hospital-farm accounts, I remain profoundly unimpressed by deficiencies based on internal book transactions.

There is actually one large-scale extravagance, which has so far escaped comment, revealed by the Ministry's Annual Report on Hospital Costing, which also gives figures for bed-occupancy rates. A general community hospital should have at least 90% bed-occupancy, and it is perfectly feasible to achieve a 93% bed-occupancy; and yet, up and down the country, there are many hospitals with only 80% occupancy and some substantially lower. Indeed, on the basis of the figures reported, there cannot be said to be any over-all shortage of hospital beds in this country. It is likely that low bed-occupancy rates reflect old-fashioned, inflexible systems of bed allocation. I am certain that attention to detail concerning this point could effect an impressive increase in the efficiency of the hospital service and a reduction in waiting-lists. A special study of this subject by the independent medical foundations—e.g., Nuffield or King's Fund—would be most opportune.

Central Middlesex Hospital,
London, N.W.10.

F. AVERY JONES.

SIR,—In his letter of May 9 Mr. McCarthy suggests that those who are now attempting to compare the maintenance costs of hospitals would do well to read Dr. Topping's article.[1] I agree, however, not for the reason given by Mr. McCarthy, but because they would be convinced of the utter futility of making comparisons of costs calculated under subjective headings of expenditure. If comparisons are to be worth anything at all, like must be compared with like. If this were done it would reveal not only such differences as Mr. McCarthy mentions but also the cost of these differences. This was, in my opinion, the basic argument of Dr. Topping's excellent article.

ADMINISTRATOR.

DIAGNOSIS OF ACUTE MENINGITIS IN INFANCY

SIR,—I wish to support the findings of Dr. Haworth in his article last week. He has done well to draw attention to the paucity of signs and symptoms in this condition. I also have been interested in this problem,

---

Each feature recorded here is discussed in the text. Serial numbers refer to the order in which the 120 patients were operated on. Three cases have been omitted from the statistical analysis: case 9 had a vestigial auricle and valvulotomy was not done; case 13 (thoracotomy only) is the same patient as case 10 (pericardial graft); case 15 (first valvulotomy) is the same patient as case 89 (second valvulotomy). Above the line are 100 consecutive patients with predominant stenosis subjected to valvulotomy alone; below it are 17 consecutive patients who had mitral stenosis but in addition significant incompetence, and in all except case 3 a pericardial graft was inserted below the mitral valve with or without previous valvulotomy.

“Left sided enlargement” is placed between inverted commas because, as explained in the text, true enlargement of the left ventricle is not differentiated from displacement of the left ventricle. Preoperative and postoperative jet refer to regurgitation felt before and after division of the commissures. The symptoms are noted as: 0, absent; +, present; 1, present on one occasion only; Cy, present only during pregnancy; Tb, tuberculosis. *Mitral 1st and pulmonary 2nd sound*: 0, not heard; N, normal; +, ++, +++, ++++, accentuated in increasing degree. *Opening snap*: 0, not heard; F, faint; +, clear. *Mitral systolic murmur*: 0, not heard; +, ++, +++, ++++, increasingly loud; AS, aortic stenosis; T, tricuspid disease. *Auricular fibrillation*: 0, not present; +, present; P, paroxysmal. Radiology of *pulmonary artery* and *left atrium*: 0, not convex; +, ++, +++, ++++, increasingly enlarged (PA + = probably within normal range; AN = aneurysmal enlargement). *Right sided enlargement* and *left sided enlargement*: 0, not observed; +, ++, increasingly great. *Intracardiac pressures*: the numerals in parentheses are right ventricular and not pulmonary arterial pressures. *Right* and *left ventricular hypertrophy*: 0, no evidence; +, ++, increasingly great. *Mitral orifice*: 1, admitting no more than finger tip; 2, admitting more than tip but no more than the third phalanx; 3, admitting more than third phalanx. *Valvulotomy*: G, good, at least one commissure was completely divided; F, fair, partial division of one or both commissures. *Preoperative* and *postoperative jet*: 0, not felt; F, faint; +, present. *Clot, calcification,* and *embolism*: 0, not present or did not occur; +, present or did occur. In all columns — indicates observation not recorded.

because most of the cases I have seen have not shown the well-known signs described in the textbooks.

I have personally treated 12 cases of acute meningitis in children under five years of age in the past three years at Dr. Steevens' Hospital; of these, 6 were aged one year or under. 2 cases were meningococcal, and 3 were pneumococcal; in 5 no organisms were isolated; and 2 were acute lymphocytic. There were no deaths.

Only 7 of these cases showed neck rigidity. Kernig's sign was never present; neither was Brudzinski's sign, being a sign only in advanced cases. Most cases had some lassitude or drowsiness, but this was not of great value diagnostically. However, in 10 cases (including those in which there was no neck stiffness) there was a definite history of vomiting.

In Dr. Haworth's series of 50 cases, vomiting occurred in 31. Vomiting appears to be the most constant early clinical manifestation of meningitis in young children. It seems reasonable to conclude that if a child (especially an infant) is vomiting with no physical signs to account for it, and is persistently unwell, a diagnostic lumbar puncture should be performed without delay.

OBSERVATIONS ON PEPTIC ULCER

SIR,—Peptic ulceration, as Sir Heneage Ogilvie implies (March 21), is a disease of civilisation, and major scientific advances have contributed few clues to its exact ætiology.

Perhaps this continuing ignorance is due to our failure to bear in mind the dual aspect of the disorder. This duality manifests itself by a rhythmic swing of the symptoms, which patient and physician alike accept as pathognomonic. The active phase takes the form of distinct "attacks" with a sharply defined onset: the diurnal epigastric discomfort, with its daily peaks related to certain phases of the digestive cycle, usually increases to a maximum after 2–3 weeks and then diminishes to disappear completely after an average of 6 weeks in untreated cases. The subsequent intermissions, in typical and uncomplicated cases, are free from epigastric discomfort related to the time of eating. Often an ulcer crater previously demonstrated by radiography can still be seen; and the impression is that the symptoms remit with or without treatment and that the discomfort then cannot be provoked, in spite of the persistence of the ulcer crater. Most observations and methods of treatment are based on the apparent chronicity of peptic ulceration, while the active stage and the periodicity are seldom considered.

The following observations on treatment are related to the unexplored active phase; it is doubtful whether they have a direct bearing on the healing of peptic ulcer in the sense of restored anatomical structure. These observations were made over a period of 5 years on 37 patients with chronic peptic ulceration who were unsuitable for, or rejected, accepted forms of medical or surgical treatment. The average history of chronic peptic ulceration was $11^{1}/_{2}$ years.

Treatment consisted in daily intramuscular injections of 500 international units of chorionic gonadotropin. A rational background to this form of treatment was provided by Harvey Cushing's writings on the hypothalamus and the parasympathetic nervous system; by the experiments of Sandweiss and his colleagues on the ulcer-preventing effect of pregnancy-urine extracts on the experimental jejunal ulcer of the Mann-Williamson dog (gastrojejunostomy and diversion of the pancreatic and biliary secretions from the duodenum to the ileum); and by the known rarity of attacks of peptic ulceration during the second half of pregnancy. No other medicines were prescribed; no dietary or other instructions were given; and the patients were told nothing of possible time or evidence of improvement.

The patients fell into three groups. The first group (28 patients) had during past attacks had adequate medical treatment (rest, Sippy diet, powders, and belladonna) but were reluctant to subject themselves again to a prolonged régime because the recurrences had become more rather than less frequent; the average length of history of peptic ulceration in this group was 11·1 years, and the average number of recurrences in each of the two preceding years 2·1; 22 patients had pronounced deformity of the duodenal cap. The second group (5 patients) wished to try one last form of medical treatment before agreeing to surgery; the average length of history in this group was $14^{1}/_{2}$ years. The third group (4 patients) were by temperament and occupation unsuited for a medical régime; the average length of history was 1 year. All 37 patients had at the time of treatment the typical ulcer pain, and the crater was in all cases radiologically demonstrated. On the 4th day of treatment (i.e., after the third injection, that is 48–72 hours from the first) 34 of the 37 patients volunteered that, having noticed no change after the first two injections, they now had complete relief. With 1 exception, these 34 patients abandoned spontaneously all customary medicines, rules, and dietary precautions. In 6 of the 34 patients the symptoms recurred after a few days, but 28 patients remained free from symptoms and unaffected by what they had known in the past to provoke pain.

Of the 28 patients who experienced lasting relief 18 have been observed for 2–5 years. These 18 (15 duodenal ulcers, 3 gastric ulcers) had an average history of 9·6 years; in 12 there was distinct deformity with a crater. The average number of recurrences in each of the two previous years was 3·4; in the 2 years following treatment it was 0·31. The results by way of lasting relief were significantly, but by no means decisively, related to the type and severity of the case. The improvement or disappearance of the radiographic signs was not always in relation to the clinical improvement.

The optimum therapeutic effect was produced by the minimum number of injections that gave relief. At the start of this investigation it was felt that injections should be continued at least until the radiological signs had disappeared. Some patients, however, had a return of the symptoms while still receiving daily injections; and they attributed further exacerbation to the injections themselves. The injections were discontinued, and the symptoms cleared. In later cases (24) a maximum of three consecutive daily injections was given.

Experience has shown that the effect of the injections cannot be enhanced by increasing the dosage or by prolonging the treatment. Three or fewer injections, given during the active phase, produced sudden and more or less lasting improvement; but when given during the phase of improvement or remission, they seemed to reactivate the ulcer process. The pattern of the response seemed constant in each individual patient. Renewed courses of treatment produced the same pattern of reaction in the 6 patients who had lost their symptoms on the 4th day but who had relapsed within a fortnight. Further courses in the 3 cases which did not respond to the initial course also failed to relieve the symptoms.

These observations suggest that the active phase of peptic ulceration is a functional aberration of the feed-back mechanism in the autonomic system, similar in principle to Gasser's classical diagram of reverberating circuits, which also was histologically demonstrated and experimentally proved by Lorente de Nó.

There are established instances of brief endocrine stimuli evoking a "step" function in the nervous system and of substances acting on the transmission of autonomic nerve impulses producing a similar endocrine effect.

Auscultation

Sir Thomas Lewis said that one should learn to recognise certain murmurs as one would the bark of a dog By auscultation mitral stenosis can often be detected in a few seconds In the diagnosis of associated mitral incompetence and similar problems the quality of the heart sounds and of added sounds and murmurs may give more information than accessory methods of investigation We believe that, when patients are being assessed for operation, more attention should be paid to the details of auscultation than has been customary in the past

HEART SOUNDS

A sudden, loud, slapping *first heart sound* at the apex is a confirmatory sign that mitral stenosis is the predominant lesion The absence of these qualities suggests either predominant incompetence, of which other evidence should be sought, or tight stenosis with a rigid valve It should be possible on other grounds to differentiate between these extremes When the first sound is obscured by a murmur, its features should be assessed by auscultation towards the mid-axillary line Towards the sternum the sound produced at the tricuspid valve may be mistaken for the mitral sound

Accentuation of the *second heart sound* in the pulmonary area is widely believed to reflect the degree of pulmonary hypertension Table II shows that in this series, whereas a loud pulmonary second sound was usually associated with severe pulmonary hypertension, there was sometimes a considerable discrepancy, and pulmonary hypertension was in some cases associated with a normal second sound The loudness of the sound may vary widely in the same person with exercise and with emotion—e g, on examination for the first time or by a new examiner, especially a surgeon It also varies with respiration and is loudest when the breath is held in expiration

Splitting of the second heart sound in the pulmonary area may be heard in healthy people, especially in youth It may also be heard in patients with mitral stenosis, particularly if the right ventricle is enlarged and there is delay in closure of the pulmonary valve More often apparent splitting is due to the opening snap of the mitral valve, which is often audible in this area although loudest at the lower left sternal border This has been proved to our satisfaction by the study of simultaneous phonocardiograms at the apex, at the left sternal border in the fourth intercostal space, and at the left sternal border in the second intercostal space (fig 2)

True *triple rhythm* is rare in patients with mitral stenosis, and is apt to be confused with an opening snap Pathological triple rhythm is of serious prognostic importance, whereas the opening snap bears no such significance It was not recorded in this series

Reference has recently been made to the significance of the *opening snap of the mitral valve* in determining whether mitral stenosis or mitral incompetence is the predominant defect when both are present (Logan and Turner 1952b) It is an *important* physical sign It may be heard more often than not in cases of mitral stenosis, whether there is normal rhythm or auricular fibrillation, and bears no relation to complications such as cardiac failure We believe that the opening snap may be absent in cases of tight stenosis with rigid or calcified cusps, but the chief points to emphasise are that in our experience, when a snap is heard, mitral incompetence is unlikely to be the predominant defect at the mitral valve, and that weakness or absence of this sound should lead to a search for other signs of mitral incompetence In the differentiation of an Austin Flint murmur from the diastolic murmur of mitral stenosis the detection of an opening snap signifies that mitral stenosis is present in addition to the aortic incompetence

The Present Series

In this series of 100 patients shown at operation to have predominant mitral stenosis a snap was heard in 87 The remaining 13 had a narrow rigid valve Of the 16 patients operated on for mitral incompetence the snap was not heard in 15, and was faint in 1 who also had moderate stenosis

HEART MURMURS

The grading of murmurs is subjective, so there can be no precision in recording their qualities Throughout the series the grading has been agreed on by the same three persons and is probably, therefore, reasonably uniform

Diastolic

The characteristic *mid-diastolic* and *presystolic* murmurs of mitral stenosis do not require detailed description here Unless tachycardia makes precise timing impossible, a distinct gap can be appreciated between the end of the second heart sound and the beginning of the mid diastolic murmur The murmur often appears to begin with the opening snap referred to above We have not found the presystolic murmur important Since it depends on auricular contraction it is absent in auricular fibrillation

An *early diastolic* murmur beginning immediately after the second heart sound is due to either aortic or pulmonary incompetence The murmur of aortic incompetence is best heard along the left sternal border, and is often audible at the apex If there are no signs of free aortic regurgitation, this murmur may be difficult or impossible to differentiate from the Graham Steell murmur of pulmonary incompetence The Graham Steell murmur is found only when there is severe pulmonary hypertension and therefore is often associated with an accentuated second sound and signs of right ventricular hypertrophy It is rarely so loud or so long as the early diastolic murmur of aortic incompetence, and is not conducted to the apex It may appear superficial in origin, and may be inconstant

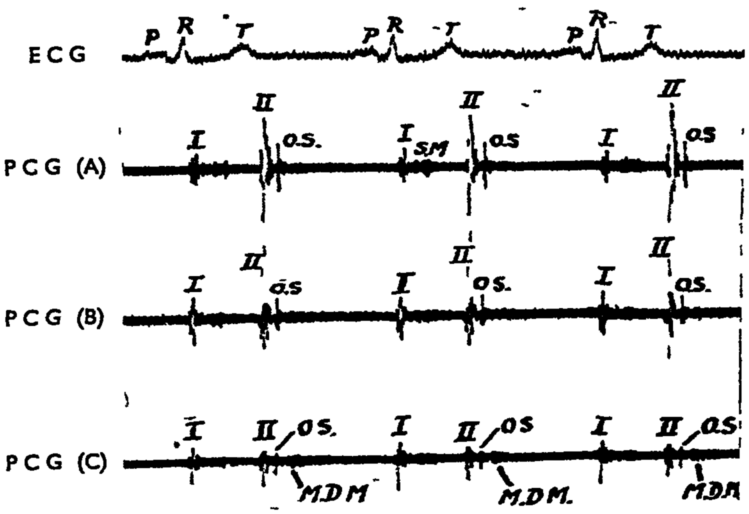

Fig 2—Phonocardiograms showing apparent splitting of pulmonary second sound due to mitral valve s opening snap, which is usually maximal at lower left sternal edge and immediately precedes mid-diastolic murmur at apex (*Frequencies were adjusted to show heart sounds clearly and not murmurs*) E C G electrocardiogram lead II, P C G (A), phonocardiogram 2nd left interspace, P C G (B), phonocardiogram 4th left interspace, P C G (C), phonocardiogram apex, I, first heart sound II, second heart sound, O S, opening snap M D M, mid-diastolic murmur S M, systolic murmur

THE ILLEGIBLE CANDIDATE

SIR,—All examiners appreciate only too well what an extra burden is imposed on them by candidates whose writing is difficult to read. There must be an unconscious prejudice against bad and illiterate handwriting, but all the examiners I have ever worked with have made it a point of honour to try to decipher what has been written and to avoid any deliberate penalisation for handwriting.

It has been left to our youngest Royal College—that of Obstetricians and Gynæcologists—to express openly the view that handwriting may lead to loss of marks. This is stated in so many words in the preamble to the examination paper for the Diploma in Obstetrics in March, 1953.

It is to be feared that candidates for higher medical examinations have already stabilised their handwriting to such an extent that not even a ukase from one or even all the Royal Colleges is likely to produce any striking improvement. Many must regret the mushroom growth of diplomas, but if these are to be made a test of handwriting as well as of a knowledge of the subject in question, the burden on doctors will be heavier than it is already.

Guy's Hospital,
London, S.E.1. J. J. CONYBEARE.

TRICHOMONAS VAGINITIS

SIR,—I have been following with interest the correspondence on this subject, and should like to state some of my observations about this common condition.

My view is that the disease is in most cases self-communicated. Every gynæcologist must have noted the unclean state of the perineum and perianal region in many women, especially the parous. A dry cotton-wool swab, drawn across the perineum, will show a faint fæcal smear even when the skin appears clean. This is especially common in women who have external pile tags, and who, either through obesity or tight low corsets, are unable to cleanse the anus efficiently after defæcation. In some women with slack anal sphincters, this fæcal contamination occurs even as a result of passing flatus. From this contaminated site the infection is carried into the vagina either by the fingers, by rubber occlusive pessaries, by masturbation, or by coitus.

Suitable instructions, including the washing of the anus with soap and water after defæcation, will prevent relapses.

London, N.W.2. M. E. LANDAU.

PHARMACEUTICAL ADVERTISEMENTS

SIR,—I should like to add to the correspondence about support of medical research by private firms in this country by drawing attention to what is done in the U.S.A. This information has been given by Deignan and Miller.[1]

The principle generally accepted in that country is that the support should be "in conformance with the research potential"—in other words that full use should be made of the research-workers available and qualified to investigate a given problem. The burden is divided between government and private sources. In the years 1946–51 a total of $135,044,125 was awarded for medical research, of which $51,933,454 (38·5%) was from private sources. Furthermore the funds from private sources increased materially towards the end of the period.

In this country it seems difficult to obtain authoritative information on this subject. Sir Reginald Watson-Jones (April 11) appears to know more than the Association of British Pharmaceutical Industry. They were unable to provide the statistics required, stating that "the financial details would normally be confidential to the firms themselves." It is unfortunate that they should be kept secret, since, as long as this is the case, suspicion and controversy are possible. Many commercial firms in this country have research laboratories of world-wide reputation, and this is certainly a good way to support research. At the same time the provision of more funds to workers in other laboratories would undoubtedly benefit the firms themselves. This is not a matter of charity: medical research is the life-blood of the pharmaceutical industries. The great expansion of their transatlantic rivals is due to a more longsighted policy.

The paper by Deignan and Miller describes a survey made by the Medical Sciences Information Exchange in America. The research potential in this country is undoubtedly great, and it would be a good thing if research-workers here could find out in a similar way about funds made available by British commercial firms.

London, S.W.18. PAMELA JEWELL.

INTESTINAL OBSTRUCTION IN INFANTS

SIR,—Dr. Sweetnam in his letter (April 4) agrees with the remark in your annotation (March 7) that the mortality from surgical conditions in children has been greatly reduced. He does not go on to acknowledge the part played in this improvement by just those special centres which he decries.

His use of intussusception and intestinal obstruction of the newborn as examples of these surgical conditions seems to me to point to the source of confusion which underlies much discussion on this subject. Intussusception is a fairly common condition in which a general surgeon operating in the excellent pædiatric units now established throughout the regions will soon obtain the experience necessary for efficient treatment. It is one of the important class of illnesses of childhood (others are pyloric stenosis and appendicitis) which are relatively frequent and for which there is an established and largely effective treatment.

Neonatal obstruction, however, is much less common. A peripheral unit is unlikely to have sufficient material to become efficient in the special techniques necessary for operation and management. It is an example of a group of conditions that are mainly congenital abnormalities and mainly require treatment in the neonatal period. Œsophageal atresia, congenital anorectal malformations, diaphragmatic hernia, and spina bifida may be cited as other conditions in this class. They are less common and their management is not yet settled. The usual surgical textbooks and teaching give little guidance in this respect. These are the cases in which the special clinics have made such great progress.

The foremost consideration is the survival of the patient. The next is the collection of knowledge about these difficult conditions. Does Dr. Sweetnam believe that either aim will be realised more frequently when these babies are cared for by surgeons who see only a few cases?

Many of these cases are urgent, and Dr. Sweetnam rightly points out the necessity for early diagnosis. Once this is achieved the few hours needed for transfer in this small country are insignificant. For instance, when intestinal obstruction is diagnosed a tube can be passed and the stomach emptied; and the baby will then withstand a journey surprisingly well.

The pædiatric surgeon is not an ultra-specialist. Rather does he extend the scope of the general surgeon to include proctological, urological, plastic, thoracic, and orthopædic conditions within this special age-group. Overlapping is inevitable, and personal interests and talents must affect individual arrangements; but in principle the completely different problems set by these patients seem to me to justify the approach.

The general surgeon has become largely a specialist in alimentary conditions. Nevertheless his older patients' behaviour will not guide him far in treating obstruction

Systolic

A systolic murmur at the apex is often heard in patients who also have signs of mitral stenosis and always signifies the possibility of predominant mitral incompetence. A systolic murmur was present in 59 of the 120 patients in the combined series.

We have limited ourselves to differentiating five grades of murmur. Grade five is rare and was not recorded in this series. Comparison has been made between the systolic murmur heard preoperatively and the regurgitant jet felt at operation (see table II). In most cases a systolic murmur presumably means that there is mitral regurgitation but this may be too faint to be appreciated by the gloved finger, and occasionally it is attributable to aortic or to tricuspid disease.

An attempt was made, by noting the qualities of the murmur, to estimate the degree of regurgitation likely to be met at operation. Of 17 cases in which a strong regurgitant jet was felt a systolic murmur of grade four intensity had been heard in 2; of grade three in 9, of grade two in 5; and in 1 case no murmur had been recorded. A loud presystolic murmur together with tachycardia sometimes makes the detection of a faint systolic murmur difficult. An apical systolic murmur was heard in 29 out of 75 cases in which no jet was felt. The absence of a palpable jet may have been due to the temporary weakening of cardiac action, which sometimes occurs during the operation. The loudness of the murmur in this group was recorded as grade one in 13 cases and as grade two in 12 cases. In 4 cases a murmur of grade three or four was recorded in spite of fairly tight stenosis, and in these the murmur, although loud, was finer and higher-pitched than the murmur of significant regurgitation.

We think that a fine high-pitched apical systolic murmur unaccompanied by other signs of mitral incompetence can be ignored. If the murmur is long, loud and harsh significant incompetence is more likely, but in our experience such a murmur is not necessarily a sign of predominant incompetence rendering the patient unsuitable for valvulotomy if in addition there is a loud slapping first heart sound or a clear opening snap.

A harsh systolic murmur at the apex is often present *in aortic stenosis* but does not mean that this is the predominant lesion. Other evidence of aortic stenosis should be sought particularly in the peripheral circulation. The aortic second heart sound is often weak or absent. The murmur of aortic stenosis may occasionally be loudest at the apex, but the same harsh systolic murmur can be recognised to the right of the upper sternum. It is usually conducted into the vessels of the neck and accompanied by a systolic thrill. An early diastolic murmur of aortic incompetence may also be heard.

A pregnant woman, aged twenty six, was seen because of severe paroxysmal pulmonary œdema. A harsh systolic murmur was heard at the apex. This murmur was loudest in the aortic area, conducted into the neck, and accompanied by a systolic thrill. It was interpreted as being due to aortic stenosis. An early diastolic murmur of aortic incompetence was also present. The aortic second sound was normal. The first heart sound at the apex was accentuated, and a mid-diastolic murmur of mitral stenosis could be distinguished. The opening snap of the mitral valve was easily heard. There were no dynamic signs of aortic incompetence in the peripheral circulation, and the pulse was of normal volume. The blood pressure was 100/60 mm Hg. At fluoroscopy in the postero-anterior view the heart was of normal size, and in the right anterior oblique view there was slight enlargement of the left atrium without systolic expansion. There was no left ventricular enlargement. The electrocardiogram indicated auricular but not ventricular hypertrophy. The mean pressure in the pulmonary artery was 28 mm Hg and there was a sharp rise on gentle exercise.

It was concluded that mitral not aortic valvular disease was the more important lesion, and that the paroxysmal dyspnœa was not due to left ventricular failure. At operation tight mitral stenosis was found and after valvulotomy her condition has been greatly improved.

Tricuspid lesions are difficult to detect, and may occur without characteristic pulsation in the veins of the neck and in the liver. If the right ventricle is enlarged, a careful search should be made for evidence of tricuspid disease, especially if the pulmonary arterial pressure is unexpectedly low. It cannot be concluded that a systolic murmur is due to tricuspid disease because it is loudest near the sternum. A study of necropsy material has shown that such a murmur may be due to mitral valvular disease when the valve is much deformed and calcified. The only means of confirmation of tricuspid incompetence during life may be by digital examination of the tricuspid valve through the right auricle, but this would be justified only by the belief that there was also enough tricuspid stenosis to require valvulotomy. One of our patients with tight calcific mitral stenosis had a loud harsh systolic murmur audible to the right of the lower sternum and maximal over the sternum. She died, and at necropsy no tricuspid lesion was evident. However, that functional tricuspid incompetence existed in life cannot be proved or disproved by examination after death.

The points to be emphasised are that there are causes of a loud apical systolic murmur other than mitral incompetence, and even a loud mitral systolic murmur does not necessarily mean that there is mitral regurgitation of dynamic significance.

Palpation

The position of the *apex-beat* is a rough and ready guide to the size of the heart, but anyone who regularly compares his clinical and radiological findings will soon be disillusioned about the accuracy of palpation in this respect, at least in cases of rheumatic heart disease.

Palpation is a valuable guide to ventricular hypertrophy, which may be present in considerable degree without much radiological evidence of enlargement of the heart, especially when hypertrophy results from increased work against resistance, as in cases of valvular stenosis. The deliberate apical thrust of left ventricular hypertrophy is unmistakable. Right ventricular hypertrophy has been said to give rise to a tapping apical impulse but many find difficulty in appreciating this quality and we consider that right ventricular hypertrophy is more readily detected by a thrust high in the epigastrium under the left costal margin or by a parasternal heave. The apical impulse may have a tapping quality without other signs of right ventricular hypertrophy, and right ventricular hypertrophy may be severe without a tapping impulse.

A *diastolic thrill* is a familiar accompaniment of the presystolic or mid-diastolic murmur of mitral stenosis. If, in addition, a *systolic thrill* is palpable it signifies that both stenosis and incompetence are present but gives no guidance as to which is the predominant lesion. A diastolic thrill from sclerosis of the cusps may be associated with a widely incompetent valve, and a systolic thrill may accompany tight mitral stenosis. The presence or absence of a thrill is of no material value in the assessment.

The Pulse

In patients with pure mitral stenosis of severe degree the pulse is characteristically small in volume. This is probably related both to the diminished cardiac output and to compensatory vasoconstriction. The hands are usually cold, and a "poor circulation" is a common complaint. If the pulse is not of this type, some complication should be sought, notably aortic or mitral incompetence. In pregnancy the pulse may be of relatively good volume, probably because of the increased blood volume.

in the newborn. For instance, indwelling gastric tubes have to be so small that they cannot be reliable. They are tolerated variably and may produce œsophageal hæmorrhage. Intravenous therapy has to be controlled on the assumption that renal function will be inefficient. The ordinary technique of two-layer anastomosis will not often be applicable. Peristalsis may be found to persist in the presence of peritonitis, and muscle-guarding to be absent under the same conditions. Experience of underlying lesions, such as errors of rotation and cystic fibrosis of the pancreas, cannot be gained from surgical treatment of adults; and yet such lesions require diagnosis by observation at laparotomy if treatment is to be adequate.

General surgical principles are the essential foundation in this as in other branches; but the foundation alone is not enough—a superstructure of experience of the individual variations of these cases is also required.

Harrow, Middlesex. H. H. NIXON.

CONTRACEPTIVE TECHNIQUE

SIR,—May I correct the misapprehensions expressed by Dr. Marie Stopes (May 2) with regard to my company's announcements on 'Preceptin Vaginal Gel'?

As international manufacturers and distributors of contraceptive jellies and creams and vaginal diaphragms, we are naturally aware of the limitations of the chemical contraceptives hitherto available, when used as a sole preventive against migration of spermatozoa through the os. These limitations are due to the inability of vegetable gums and emulsified fats to adhere closely to a secreting surface and so provide the necessary "barrier" to the cervical os. For this reason the "diaphragm and jelly" technique has been accepted as hitherto the most effective measure because the diaphragm provides both a physical barrier and a means of holding a sufficient quantity of the spermicide close to the cervix. But there are cases where the diaphragm either cannot or will not be used. Further, any means of conception control depends on intelligent use. Acceptability to the patient is no small factor in success.

More than eight years' research in the Ortho Research Foundation was concentrated on the development of a simpler method that would be at least as effective as the use of a diaphragm. The release of preceptin vaginal gel was preceded by two years' study involving thousands of patients, and the resultant high degree of success reported in these earlier studies has since been widely confirmed in many countries. The preparation succeeds, where other chemical contraceptives have failed, because it is neither a jelly nor a cream but is compounded in a base of unique synthetic materials having the ability to adhere tenaciously to a moist secreting mucosal surface. It provides its own "barrier" when 5 ml. is deposited at the cervix. The synthetic base also has the power to release the active spermicidal system more rapidly than has been possible even with such highly spermicidal compounds as 'Ortho-gynol' jelly, which is compounded in a vegetable gum base.

Mechanical devices solve only part of the vast problem of contraception. The acceptance of the mechanical barrier as the final achievement of science takes no account of such resources as those of the Ortho Research Foundation, with which my company is associated.

ANTICOAGULANT DRUGS

SIR,—Are anticoagulant drugs a benefit or otherwise to our patients? I am prompted to ask this question owing to the wide divergence of opinion held by two great schools in their treatment of acute deep-vein thrombophlebitis.

On the one hand, the Swedish school presents us with statistics showing a great diminution in the occurrence of embolism, and a speedy resolution of thrombophlebitis, when heparin and drugs of the dicoumarol series are employed. On the other hand, the Manchester school takes an opposite view. Professor Boyd suggests that anticoagulants have no place in the treatment of acute thrombophlebitis, and he is of the opinion that dicoumarol is an extremely dangerous capillary poison which, when administered to patients with ischæmia, may cause eruptions of the skin followed by sloughing. He tells me that recently in six cases he has had to amputate legs which might have been saved had this drug not been given. He makes the suggestion that heparin tends to loosen recently deposited soft clots, and in support of this view states that in twenty-five years he had never found bona-fide embolism following deep vein thrombophlebitis, but in recent years has come across such cases in patients receiving anticoagulants. Cases of acute deep-vein thrombophlebitis in their earliest stage are treated by the Manchester school by means of paravertebral block, and all anticoagulants are anathema.

This makes me ask the question—are anticoagulants our friends or our foes? Your readers' views on this most important subject would be valuable. It is fully time that the treatment of deep-vein thrombophlebitis was standardised, since all will agree that crippling sequelæ are all too common. The country has a vast population of patients with severe ulceration of the legs, which might well not have arisen had the antecedent condition of deep-vein thrombophlebitis been promptly and correctly treated.

London, W.1. R. ROWDEN FOOTE.

SUCKLING

SIR,—To suckle is a transitive verb meaning to give suck to (*Concise Oxford Dictionary*). In your leader on Puerperal Mastitis (May 2) you state that a procedure "allows the baby to . . . suckle normally"—which is a wrong use of the verb. Your next sentence uses it correctly in speaking of "pain on suckling"; for suckling is what the mother who feels the pain does. The infant feeds, takes the breast, or sucks.

Guy's Hospital, London, S.E.1 RONALD MAC KEITH.

UTERINE CANCER AND VAGINAL SMEARS

SIR,—Like Dr. Osborn (May 2) I was surprised at the misapprehensions in your leading article of April 18, and I was glad to find such support for cytology from a pathologist. We too have passed the 5000 mark, and the assessment of results of 3000 is shortly to be published.

I agree with Dr. Osborn in nearly every respect. But I believe that expansion of this work, which many of us have come to regard as essential, depends on its being largely carried out by technicians, if for no other reason than that there are not enough pathologists. This has been abundantly shown in the U.S.A., and there is no doubt that it is perfectly feasible. The negative smears are screened out by technicians, who can achieve this competence in six months, and the difficult and positive ones are kept aside. The laboratory is in the gynæcology department, and we cater for the pathology in this subject for the whole region.

I should have liked to see Dr. Osborn divide cancer of the uterus into its two types—cervical and corporeal. We find that our most useful contribution is in cervical cancer, where we can show just under 1% of women coming to our gynæcological clinics to have a cancer not suspected by the gynæcologist after speculum examination. But in the matter of body carcinoma, well known to be more difficult, we find it almost impossible to compete with curettage, which is usually so speedily arranged that we contribute very little, though we have had a few discoveries.

With Miss Mary Egerton I also agree—the value of the method is not assessable by the cost of working hours. And it is usually forgotten that the 499 patients who

Examination of the Lungs

When there is pulmonary œdema, or soon after hæmoptysis, crepitations may be heard in the lungs. There may be no crepitations although there are signs of congestive cardiac failure in the peripheral circulation. Abnormal signs may be caused by pulmonary infarction or by hydrothorax secondary to either infarction or cardiac failure. Attacks of acute bronchitis are common in patients with mitral stenosis, quite apart from the signs of "bronchitis" in the form of rhonchi which may accompany œdema.

We have been struck by the infrequency of radiological signs of hilar congestion or of congestion in the peripheral parts of the lungs in patients with mitral stenosis. This may be related to the fact that "hilar congestion" is usually due not to increased vascular markings but to pulmonary œdema; and in mitral stenosis this is rarely present except in acute attacks, whereas in left ventricular failure it may be chronic. Pulmonary arteriosclerosis, which is often present in mitral stenosis, may perhaps prevent or mask pulmonary congestion. Possibly the volume of blood in the lungs is not increased as is commonly supposed.

Cyanosis

Cyanosis may be central or peripheral in origin. Central cyanosis does not occur unless the disability is very severe and of long standing. It is due to deficient oxygenation of the blood as a consequence of the alveolar changes of prolonged pulmonary congestion. Peripheral cyanosis is due to stagnation secondary to vasoconstriction, and the arterial oxygen saturation is normal. Cyanosis is not in itself a sign of cardiac failure; when it is accompanied by clubbing of the fingers, some complication unrelated to rheumatic heart-disease should be sought. In 1 patient in this series cyanosis was due to a shunt in bilateral congenital arteriovenous aneurysms in the lung (case 57).

Auricular Fibrillation

Sooner or later, auricular fibrillation develops in most patients with mitral stenosis. Of 100 patients operated on for predominant stenosis 40 had established auricular fibrillation or had experienced paroxysmal attacks. In 17 cases with predominant incompetence auricular fibrillation was present in 9. The exact cause is obscure, and we have been unable to demonstrate any close relation with other factors, such as the severity of the stenosis, the degree of pulmonary hypertension, and the size of the left atrium. On the other hand, the incidence of fibrillation increases as age advances, and it is common in those with large hearts. Involvement of the myocardium by the rheumatic process is probably the most important cause. Precipitating factors include exacerbations of rheumatic carditis, acute infections, and sometimes, apparently, exertion. The onset of fibrillation may be shortly followed by acute cardiac failure, thrombus formation in the heart, and pulmonary or systemic embolism. The heart-rate should be rapidly controlled. When a precipitating factor can be identified the question of attempting to restore normal rhythm will sometimes arise. In most cases this is not worth while, because of the likelihood of an early return to fibrillation.

Paroxysmal fibrillation usually means that fibrillation will shortly become established. Repeated episodes of fibrillation are distressing to the patient, and established fibrillation with the rate controlled by digitalis is often preferable. Fibrillation, however, means a less competent heart and a greater likelihood of embolism. In some cases it is possible to prevent further attacks and to postpone the establishment of fibrillation by the regular administration of quinidine.

If acute carditis can be excluded, the onset of auricular fibrillation is an indication for considering operation on the grounds that it is evidence of progression of the disease; and, in theory at least, the mechanical disadvantage of auricular fibrillation will be to some extent offset by reduced obstruction at the mitral valve. Cardiotomy may offer the opportunity of emptying the auricle or the atrium of clot, and thus of diminishing the risk of systemic embolism. Moreover, when it is known that no clot remains in the atrium, the restoration of normal rhythm may be considered.

The problem of whether to restore normal rhythm in cases of recent auricular fibrillation in patients considered suitable for operation also arises. In recent years it has been widely believed that the risk of embolism after restoration of normal rhythm with quinidine has been exaggerated, and that the risk of further thrombus formation and embolism is greater while auricular fibrillation persists. Statistically this may be true, but one is bound to be influenced by the individual case.

A patient referred from another hospital was first seen three weeks after the onset of auricular fibrillation and put on the waiting list for admission with a view to assessment. In the meantime it was recommended that normal rhythm should be restored with quinidine. This was achieved without difficulty, but forty-eight hours later he developed a hemiplegia from cerebral embolism.

In such cases, when operation is necessary it is probably better done before an attempt is made to restore normal rhythm, so that any loose clot is removed from the auricle and atrium.

Although auricular fibrillation is usually a sign of severe myocardial damage, and predisposes to the formation of clot which may be dislodged into the systemic circulation during operation, it is not in itself a contra-indication to operation.

After successful valvulotomy the question of restoring normal rhythm again arises. In most of our patients with well established fibrillation before operation we have not thought this advisable. In 2 the attempt was successful, but in 2 the arrhythmia proved resistant even to high dosage of quinidine (4 g. per day). If age and rheumatic myocarditis are the principal causes, the arrhythmia will soon return. Of the 40 patients with auricular fibrillation who were subjected to valvulotomy 25 were aged more than forty. However, if there is a history of embolism, and the auricle and atrium are found at operation to be free from clot, and the valvulotomy is satisfactory, restoration of normal rhythm may be a reasonable prophylactic measure against further embolism.

Patients with auricular fibrillation do not have electrocardiographic evidence of right ventricular hypertrophy as often as those with normal rhythm. Although tight mitral stenosis was present in 34 of the 35 patients with auricular fibrillation in whom pressures were recorded, pulmonary hypertension was moderate in most cases, and severe in only 4. This may explain why recurrent hæmoptysis and paroxysmal dyspnœa were rare in this group. Attacks of breathlessness associated with paroxysmal fibrillation did occur but *not* typical paroxysmal nocturnal dyspnœa or pulmonary œdema.

9 of the 17 patients with predominant incompetence had auricular fibrillation and of these none had electrocardiographic evidence of right ventricular hypertrophy and 2 had evidence of left ventricular hypertrophy.

Postoperative auricular fibrillation in those who previously had sinus rhythm is common and occurred in 19 of this series. It was not a cause of *immediate* anxiety, because the heart rate was readily controlled with digitalis; but we feared that it might predispose to thrombus formation in the heart, especially on the auricular suture line. We therefore took steps to restore sinus rhythm with quinidine as soon as possible, and this was achieved in all cases. One patient, who reverted to fibrillation after returning home, died from cerebral have negative cytology are benefited to some degree, as well as the 500th who has a positive answer and is successfully treated.

TUBERCULOSIS IN GLASGOW

SIR,—It is incredible that Dr. Horace Joules can expect anyone to take seriously his letter in your issue of May 2 criticising tuberculosis administration in Glasgow on the basis of a fleeting visit and a view of one "unselected" patient suffering from pneumonia. Before he presented evidence, it appears to us that he would have been well advised to consult the senior administrative medical officer of the Western Regional Hospital Board and the medical officer of health of the city. This might have prevented him from making inaccurate statements. He says: "I learn that no consultant in tuberculosis has yet been appointed to the whole region of South-West Scotland, of which Glasgow is the centre." This is not true, as there are no fewer than 14 tuberculosis consultants in the area, of whom 6 are within the City of Glasgow itself, and the board are at present in process of appointing 3 further consultants for Glasgow.

Dr. Joules also failed to make inquiry regarding the B.C.G. scheme which is the largest and most progressive in the United Kingdom, nor did he ascertain that the city had the best and purest milk-supply in the country.

We can certainly agree when he says that it may be thought impertinent for someone from the South of England to make comments on the situation. The impression he has left in this city is that as an authority on Glasgow Dr. Joules may justly claim a status approximately equivalent to that of the gentleman who moralised on the problems of India, inspired by personal experience of them acquired from a conversation held on his doorstep in the Gorbals with a Hindu pedlar who spoke broken English.

For your readers who are interested in the progress which the city is making towards the eradication of tuberculosis, the following figures are offered as evidence:

Year	*Deaths from pulmonary tuberculosis*
1949	1093
1950	930
1951	674
1952	556

No-one denies that the housing problem in Glasgow is extremely serious, the reason being that over the last century the population of the city has quadrupled. Since 1919 Glasgow Corporation have constructed over 80,000 houses, which, considering that the period included the war years, is no mean effort.

The standard of work in the tuberculosis service in Glasgow is high, but the problems which have to be met are extremely difficult. Thoughtless and uninformed criticism is no helpful contribution.

STUART LAIDLAW
Medical officer of health

J. S. GEMMILL
Glasgow. Principal medical officer (tuberculosis).

SIR,—It is not impertinent for Dr. Joules (May 2) to make comments on the housing situation in Glasgow and its effects. What is lamentable is that he does not know that successive Governments in London have failed to do anything about it. The Government elected in 1945 preferred to fritter away its energies on a Festival Hall for London, whilst the amount of timber in London today is surprising in view of the housing shortage. I feel that in "Government circles" there is lacking any will to tackle this problem, and if there is ever to be any real improvement in Scottish housing it must be made by a Parliament sitting in Edinburgh. I commend this solution to Dr. Joules.

AN ARDENT SCOTTISH NATIONALIST.

POLIOMYELITIS

SIR,—Dr. Ritchie Russell (May 2) pleads with his orthopædic colleagues "to widen their thoughts beyond muscle resting and the avoidance of deformity"; he is in no doubt that the current orthopædic practice is to discourage activity in weak muscles for several months after the onset of poliomyelitis. As a plan is afoot for comparing the results of treatment under different physiotherapeutic régimes, I asked him to give me the name of any orthopædic hospital or department in the country where this is the practice. Alas, he was unable to give me the name of one; perhaps some reader of THE LANCET may be able to help, since we are anxious to know something about the progress of recovery in patients treated by surgeons who are persuaded of the value of rest for muscles weakened or paralysed by poliomyelitis.

Dr. Ritchie Russell is under the erroneous impression that such opposition as there has been to the strenuous treatment he advocates is due to the rigid conservatism of orthopædic surgeons. My own criticism of the treatment recently described in his book, shared by many of my brethren, is simply that he has failed to produce any evidence of its value. The experiments he describes were uncontrolled, documentation was sketchy, and the most favourable conclusion that can be drawn from the account of his work is that the patients suffered no harm. The onus of proof is on him, and he may be confident that if he can show that exercise to the point of complete fatigue of a weak muscle is better than other forms of neuromuscular re-education, we shall be no less grateful to him than we already are for his convincing work on the rôle of fatigue in aggravating the extent and severity of damage to motor neurones during the stage of invasion.

Dr. Ritchie Russell seems to be driving himself too hard in endeavouring to refute evidence that casts doubt on the safety of the method of treatment he champions. In his letter of April 25 Mr. Geoffrey Hyman described a case in which violent exercise appeared to aggravate the paralysis during the stage of recovery. Dr. Ritchie Russell suggests that this relapse was caused by a second attack of poliomyelitis, the virus being of a different strain from that causing the initial attack. If it really is possible that poliomyelitis viruses of different strains hunt in packs, then he should be the first to discourage violent therapeutic exercise, for he has shown how harmful it can be at the onset of the first attack—and why not the second?

In 1948 Dr. Ritchie Russell and I went together to the first international conference on poliomyelitis in New York. In a discussion on methods of treatment during the phase of recovery, I referred to a few patients, treated at the Wingfield-Morris Orthopædic Hospital in 1947, whom I had allowed to get up early and exercise themselves fairly freely, though to nothing like the extent he advocates. The affected muscles were examined at weekly intervals and a number of them, but not all, became much weaker. The tempo of exercises was then reduced, and walking was forbidden; the muscles slowly returned to their former state, and in the course of time became a little stronger than before. At that time he did not suggest that these patients must have suffered second attacks of the disease; he said nothing at all. The chairman at this discussion knew me well enough to say that the only cause for surprise was that I had been unwise enough to embark on the experiment at all. Since then I have been more cautious, yet even so we have several more fully documented cases in which muscles have lost power when the load on them (we should say on their neurones) was rapidly increased.

Royal National Orthopædic Hospital,
London, W.1. H. J. SEDDON.

embolism. At necropsy clot was found in the auricle although none had been observed at operation.

Radiography

THE HEART AND VESSELS

The size of the heart cannot be accurately estimated by clinical examination alone. Since the left atrium is at the back of the heart no information can be obtained about the size of this important chamber without radiography. To estimate the degree of cardiac enlargement as slight, moderate, or considerable is to formulate a rough impression of the severity of the underlying cardiac disease. This estimate of general enlargement usually refers to the transverse diameter of the heart—i.e., to the shadow of the right atrium, right ventricle and left ventricle. It is not, however, sufficient to say that the heart is enlarged; one must decide which chambers are enlarged and to what degree.

The condition of the aorta, of the pulmonary artery and its main branches, and of the lung fields should be noted.

When severe mitral stenosis develops early in life, the *aorta* is much smaller than normal. Presumably this is related either to failure of development or to "disuse atrophy" from the diminished output of the left ventricle. When there is also aortic incompetence the aorta may be enlarged and may show excessive pulsation.

The size of the *pulmonary artery* does not reflect closely the degree of pulmonary hypertension (table II). Duration of the hypertension is probably important. In this series, when the artery was considerably enlarged, mitral stenosis was usually severe and the pulmonary arterial pressure was high. In only 3 cases was the pulmonary artery enlarged to the degree commonly seen in other conditions, such as interatrial septal defect.

The prominence on the left cardiac border next below the pulmonary artery in the postero-anterior view is formed by the *left auricle* (auricular appendix) and not, as is still widely believed, by the outflow tract of the right ventricle (fig. 3). Visibility of the auricle suggests that an easy approach to the mitral valve will be available, and in some cases in which the characteristic convexity has been absent the small size of the auricle has prevented the use of the auricular route. The shadow of the left atrium can nearly always be seen behind the right atrium in the anterior view, and in this position its size may sometimes be better appreciated than in the customary right anterior oblique position. We have not found that the size of the left atrium is a reliable guide to whether mitral stenosis or incompetence is likely to be the predominant defect.

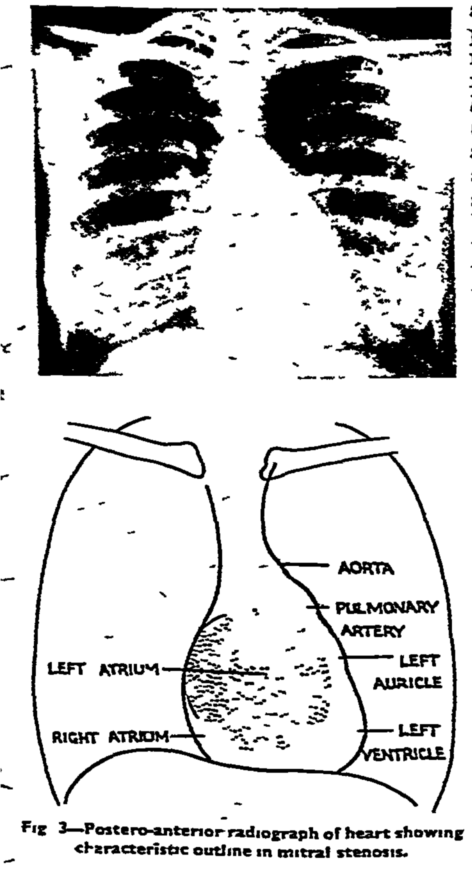

Fig 3—Postero-anterior radiograph of heart showing characteristic outline in mitral stenosis.

With increasing experience we have found it less and not more easy to differentiate minor degrees of enlargement of the various cardiac chambers. The size of the *right atrium* is best noted in the postero-anterior view, and that of the *right ventricle* in the left anterior oblique view. The right ventricle may be considerably enlarged when there is no electrocardiographic evidence of hypertrophy. The right atrium may be displaced to the right by an enlarged right ventricle. When these two chambers are both enlarged, fusion of the two curves in the left anterior oblique view may make their differentiation impossible. We now usually refer to the presence or absence of right-sided enlargement. When right-sided enlargement is marked there is probably considerable pulmonary arteriolar resistance, tricuspid disease or severe myocardial damage. When the right ventricle is enlarged, as is often the case, it may be difficult to differentiate enlargement of the *left ventricle* (as in mitral incompetence) from displacement of the left ventricle to the left in the postero-anterior view or backwards in the left anterior oblique view by the right ventricle. In these circumstances radiology is of less value than clinical or electrocardiographic assessment.

In other cases we have sometimes thought that considerable left ventricular enlargement made the differentiation of right-sided enlargement impossible, but for obvious reasons such cases are not usually under consideration for valvulotomy.

Calcification may be detected in the cusps or in the ring of the valve. Advantage may be taken of this to compare the movement of the mitral valve with that of the barium-filled œsophagus outlining the posterior border of the left atrium in the right anterior oblique view. Movement in the same direction in patients with pure mitral stenosis has strengthened our conviction that upward movement of the anterior cusp of the mitral valve into the atrium contributes to systolic expansion of the atrium, which is not therefore necessarily a sign of mitral incompetence as has been claimed.

So-called *systolic expansion of the left atrium* has already been discussed in some detail (Logan and Turner 1952b). Systolic expansion should be sought on the right and left cardiac borders in the anterior view, and in the right and left anterior oblique views, and by noting whether in the anteroposterior view the right atrium and barium-filled œsophagus move in opposite directions and, when the opportunity offers, whether the calcified mitral valve and the posterior border of the left atrium move in the same direction. Severe systolic expansion certainly suggests the presence of mitral incompetence, but the diagnosis can then readily be made on other grounds. We have observed gross expansion in all views in a patient with pure stenosis. Moderate systolic expansion may be observed in mitral stenosis, in mitral incompetence, and when these two defects are combined. Slight systolic expansion may be present in mitral valvular disease and occasionally in people with apparently normal hearts, and is of no value as a radiological sign.

THE LUNGS

We have found that radiological signs of pulmonary congestion, by which is usually meant increased vascular markings, are uncommon in patients with mitral stenosis and are of little help as a guide to pulmonary hypertension or cardiac failure. We have come to appreciate that the range of normal is wide.

It must be remembered that the depth of lung tissue in the anterior view is greatest towards the hilum; this may explain why the characteristic hazy opacities

Obituary

ROBERT GEORGE ARCHIBALD

Kt., C.M.G., D.S.O., M.D. Edin., Major R.A.M.C. retd

ALL those interested in tropical medicine or tropical agriculture will have read with regret the announcement in our columns last week of the death of Sir Robert Archibald on May 2.

He was born in 1880, the son of the Rev. W. F. Archibald of Edinburgh, a well-known Presbyterian chaplain to the Forces. From Dollar Academy he went on to Edinburgh University, where he graduated M.B. in 1902. After holding house-appointments in Liverpool, he entered the R.A.M.C. in 1906 and in the following year he was seconded for service under Sir David Bruce on the Royal Society's commission on sleeping-sickness. In Uganda he found himself in congenial company and he spent many eventful days with his fellow officer, Captain A. E. Hamerton, in hunting big game. Soon afterwards he was transferred to the Sudan, where he had his first taste of active service in operations on the Blue Nile. The next seven years he spent as a regimental medical officer with Sudanese troops, and it was this experience that gave him his knowledge of Arabic and insight into the character of this virile people.

At the outbreak of the first world war Archibald was recalled to the regular Army and in 1915 he was posted as chief of the laboratories at Mudros with the rank of major. The results of his investigations into the epidemics of dysentery and enteric in Gallipoli were published in two detailed papers in 1916. His chief problem was the correct diagnosis of the devastating dysenteries which assumed such formidable proportions. He concluded that both amœbic and bacillary forms were present, the former prevailing from June to October, and that after October the epidemic became entirely bacillary. The extensive studies on the paratyphoid fevers which he also undertook paved the way to the introduction of T.A.B. as a prophylactic vaccine.

In 1920 Archibald retired from the Army to become director of the Wellcome Research Laboratories in Khartoum, and eight years later he took over the new Stack Research Laboratories also in that city. When he left the Sudan in 1936 on reaching the age-limit he returned to Britain, and during the late war he worked in a public-health laboratory in Dorset. But once again Egypt called and though he was in his sixties, in 1947 he accepted an invitation to become professor of bacteriology in the Farouk University at Alexandria. During the last three years he had moved to the parasitological department.

During his time in the Sudan Archibald published over forty papers dealing with the diseases of that region.

Attracted at first by the problem of kala-azar, he described some coccal bodies, in association with leishmania, and he succeeded in transmitting the disease to cercopithecus monkeys. Later, he described its treatment with tartar emetic and recorded a fatal case after antimony, as well as one spontaneous recovery. In 1917, on an expedition to Darfur in the South Sudan, he observed some cases of seven-day fever. About this time he became interested in fungus diseases, and he described the pathology of mycetoma with special reference to "Russell's bodies." In 1922 he discovered the presence of *Trypanosoma rhodesiense* in the South Sudan. From 1932 to 1934 he studied the epidemiology of schistosomiasis, verified its treatment by tartar emetic, as established by Christopherson, and described the minute anatomy of the cecariæ of *Schistosoma hæmatobium* and *S. mansoni*. He also discovered the molluscicidal properties of a tree (*Balanites ægyptiaca*) which flourished in irrigated areas: its nuts and branches give out a substance lethal to fresh-water snails which promised a practical means of controlling the spread of schistosomiasis.

Perhaps his most important literary work was his editorship, together with his fellow officer and colleague, W. B. Byam, of that authoritative work the *Practice of Medicine in the Tropics*, to which he contributed the section on laboratory methods. Agricultural parasitology in the Sudan owes much to his investigations on the black-arm disease of cotton and the sulphuric-acid treatment of cotton-seed. His services were recognised by the government, and he was awarded the order of the 4th class Medjidieh and the 2nd class Nile. He was also appointed D.S.O. in 1917 and C.M.G. in 1928, and he was knighted in 1934.

P. H. M.-B. writes: "Archibald was a handsome, friendly, and imposing Scot, a typical healthy outdoors man, fond of all manly sports. No-one could fail to recognise the great qualities which marked him out as one of that select band who created the modern Sudan, and in this he followed in the footsteps of his friend and predecessor, Sir Andrew Balfour."

O. F. H. A. writes: "Archie, as he was universall called, and I served together in the Sudan for 26 years During the last 11 years of this time we worked in clos collaboration, he as director of the Wellcome Research Laboratories and I as director of medical services. I was during this latter period especially that I learnt to value his great qualities of unremitting methodical work and tireless devotion to duty, and in all eventualitie to rely on his friendship—a friendship readily extended to all. I think few men in the Sudan have gained such respect and affection as were given to him. In the seclusion of his laboratories and work he became to those who had never seen him an almost legendary figure."

He married, in 1919, Olive Chapman, only daughter of Arthur Cant, and they had two daughters.

Births, Marriages, and Deaths

BIRTHS

BENIANS.—On April 27, at Bradford, to Edith, wife of Dr. Richard Benians—a daughter.

DUFF.—On May 5 to Audrey (née Heaton-Smith) wife of Dr. A. Dewar Duff, 5, Tanza Road, N.W.3—a daughter (Elizabeth Anne).

GILL.—On April 27, at Godalming, to Aileen, wife of Mr. W. G. Gill, M.A., M.CHIR., F.R.C.S.—a daughter.

DEATH

MACBETH.—On May 9, Alison Nicol Macbeth, M.B., B.S., aged 56.

Appointments

ARCHER, NORA, M.A., D.M. Oxfd, D.P.H.: asst. M.O.H. and school M.O., Bristol.

CUTHBERT, J. M., M.B. Glasg., D.P.A.: medical superintendent to the boards of management for the Angus hospitals, and the Stracathro and Brechin hospitals.

DAVIES, J. B. M., M.D. Lond., D.P.H.: deputy M.O.H. and deputy port M.O., Liverpool.

DONELAN, M. J., M.B. N.U.I., D.P.H.: senior asst. M.O., Derbyshire County Council.

FRANCIS S. G. M., M.B. Edin.: group medical superintendent, Royal Infirmary of Edinburgh, and associated hospitals.

HALL, T. S., M.B.E., M.D., B.SC. Belf. D.P.H., D.OBST.: M.O.H. and school M.O., Salop County Council.

HOARE, R. D., M.B. Lond., D.M.R.D.: neuroradiologist, The Hospital for Sick Children, Great Ormond Street, London.

KEAY, K. R., M.D. St. And., M.R.C.P.E.: appointed factory doctor, Kirriemuir, Angus.

MAUGHAN, J. H., M.B. Durh., D.P.H.: deputy M.O.H. and deputy school M.O., Bournemouth.

MORRISSEY, W. J., M.B. N.U.I., D.P.H.: asst. M.O., Derbyshire County Council, and M.O.H., urban districts of Ashbourne and Belper and the rural district of Belper.

SMITH, THOMAS, M.B. Glasg., F.R.C.S.E., M.R.C.O.G.: part-time consultant obstetrician and gynæcologist, Jessop Hospital for Women, Sheffield.

SUTTON, DAVID, M.D. Manc., M.R.C.P., D.M.R.D.: (consultant) asst. director, diagnostic radiological department, St. Mary's Hospital, London.

WHITEHEAD, J. P. S., M.R.C.S.: asst. pathologist (S.H.M.O.), hospitals in the Scarborough, *Bridlington, Malton,* and Whitby H.M.C. group.

Sheffield Regional Hospital Board:

ADDIS, H. S. C., M.A., M.B. Camb., M.R.C.P.: consultant chest physician, Sheffield area.

BROWNE, MARGARET, M.B. Edin., D.A.: consultant anæsthetist, hospitals in the Nottingham area.

LETT, ZOLTAN, M.D. Czechoslovakia, D.A.: asst. anæsthetist, Mansfield area.

TANENBAUM, JULIUS, M.D. Paris: asst. chest physician, Mansfield area.

TOWNSHEND, R. H., M.B., B.SC. Manc., M.R.C.P., D.T.M.&H.: consultant chest physician, Sheffield area.

of pulmonary œdema are usually densest in the circumhilar region These opacities are important to recognise because, except in pregnancy, they signify severe mitral stenosis. Radiological signs may persist for several days or longer after the clinical attack of pulmonary œdema is over

If pulmonary hypertension is of long standing, the pulmonary artery and its main branches may increase in size and become denser

Some patients in this series showed radiological changes compatible with mild hæmosiderosis, which was confirmed histologically in operation specimens, but this study is incomplete Changes due to pulmonary infarction—e g , irregular or linear opacities, high diaphragm, and pleural effusion—will not be discussed further Mottling due to blood in the alveoli may be seen after hæmoptysis Hydrothorax may be secondary to cardiac failure

Electrocardiography

A detailed electrocardiographic study is being made of the patients in this series, but in summary it may be said that, although electrocardiography may not give information of material value in making the assessment for operation, sometimes it gives useful supporting evidence Since the left ventricle is never hypertrophied in pure mitral stenosis, electrocardiographic evidence of such changes, however slight, means that there is some important complication usually aortic valvular disease, mitral incompetence, or systemic hypertension For reasons which are still obscure, even clinically manifest ventricular hypertrophy may not give electrocardiographic signs In this series changes indicating pure right ventricular hypertrophy were found in 36 patients, all of whom had tight stenosis (fig 4*a*) An important corollary is that evidence of pure right ventricular hypertrophy has meant that predominant mitral incompetence was not present despite other suggestive signs such as a loud systolic murmur Patients in this group are most suitable for valvulotomy, and after operation there may be a progressive decrease in the electrocardiographic signs of right ventricular hypertrophy (fig 4*b*) Sometimes there is evidence of old rheumatic myocarditis Signs of auricular hypertrophy were present in 95% of those with sinus rhythm

Cardiac Catheterisation

Most of the patients in this series were subjected to cardiac catheterisation as part of the assessment for operation By this technique it is possible to measure the pressures in the right atrium and the right ventricle, in the pulmonary artery and its main branches, and in the pulmonary capillaries It is generally held that the capillary reading, which is made with the catheter inserted as far as possible into a branch of the pulmonary artery, reflects the approximate pressure in the left atrium (fig 5), and a sample of blood withdrawn while the catheter is in this position is arterial in oxygen content The cardiac output can be estimated according to the Fick principle From these findings can be calculated the resistance to blood flow at the mitral valve and in the pulmonary arterioles, and the approximate area of the mitral orifice Some consider that the shape of the capillary-pressure curve may provide evidence of mitral incompetence, but we have found this unreliable The blood volume and the circulation rate can also be measured To do all this with accuracy requires not only time but also organisation and technical assistance of a high standard It is important that these observations should be made in a few cardiac centres where equipment and staff are adequate to further our understanding of the hæmodynamics of valvular heart disease From the patient's point of view little more is entailed than the minor discomfort of venesection

We have usually restricted ourselves to simple measurements of pressure It was considered desirable to form our own conclusions about the value of this procedure The opportunity has been taken to correlate various physical, radiological, and electrocardiographic signs with the degree of pulmonary hypertension

Early in this series mean pressures were measured with a saline manometer Now systolic, diastolic, and mean pressures are measured with an electromanometer and recorded photographically

The pulmonary arterial pressure was recorded at rest and, if hypertension was not severe, after exercise Although patients with mitral stenosis are restricted in their activities, most of them are not at rest throughout the day, and it is the range of pressure which is important. Exercise consisted in pedalling against motor-cycle pumps and was stopped if the pressure rose promptly, because it was desired to determine only whether the pressure would in fact rise, there being no rise on exercise in normal people Since the exercise was not graded and patients vary considerably in the vigour with which they carry it out, these figures are not comparable but serve as a rough guide Probably several minutes should be allowed for a steady level to be reached , and, although this may be necessary for strictly comparable studies to be made, it was not necessary for our purpose in this series The pulmonary artery-pulmonary capillary gradient was used as a measure of pulmonary arteriolar resistance The importance of this is discussed below

With a view to allaying anxiety, '*Sodium amytal*' gr 3–6 was given to many of our patients, perhaps unnecessarily since none was obviously distressed by the procedure The effect of sedation, even when the dose was adjusted to the body-weight, varied greatly Some patients became so sleepy that pressures must indeed have been basal, and the patients were with difficulty persuaded to exercise In others some latent anxiety may not have been allayed , and, since we have found that emotion has a great influence on pulmonary arterial pressure, comparable results may not have been obtained The sodium amytal may also have had some effect in reducing a raised pressure, but this point was not determined Now we do not give a sedative as a routine

Because of these inconstant factors much attention should not be paid to the exact pressures recorded in comparing one patient with another, and patients are best divided into three groups according to whether pulmonary hypertension is mild, moderate, or severe The pressure may vary from day to day , it is certainly raised by exertion, emotion, coughing, straining, and discomfort Quinidine was given, before catheterisation, to diminish the risk of precipitating an arrhythmia

From these studies we have acquired much useful information and gained insight into many aspects of mitral valvular disease A decision whether to operate or not can often be made on clinical grounds supplemented by the readily accessible ancillary methods of radiology and electrocardiography Sometimes, however, the decision has been materially influenced by knowledge of the pulmonary arterial pressure A higher pulmonary arterial pressure at rest than had been expected, or a pressure which rose promptly on mild exertion, supported a decision to advise valvulotomy in a patient about whom we were uncertain on clinical grounds, whereas a low pressure that did not rise on exertion had the opposite effect We have not recommended operation in patients with a normal pulmonary arterial pressure which does not rise on exertion Except in 1 instance (case 49) no patient with predominant mitral incompetence has had a mean pulmonary arterial pressure above 50 mm Hg and in only 2 was the pressure above 40 mm Hg

Pulmonary Hypertension

Pulmonary hypertension is one measure of the severity of mitral stenosis and is probably a guide to prognosis In our experience patients with high pulmonary arterial pressures have been severely disabled, many pursuing a rapid downhill course, but they have also shown the most gratifying results after valvulotomy The highest pressures are not found in those with the largest hearts

Notes and News

ROYAL DENTAL HOSPITAL

At the 36th annual clinical At Home of the Royal Dental Hospital, held last Saturday, the demonstrations covered all aspects of dental surgery, and reflected much recent progress in orthodontic diagnosis. Methods of treatment have been modified now that a clearer picture has been gained of the factors—e.g., skeletal and muscle patterns, and the bad habits of thumb and lip sucking—which make for an unfavourable prognosis. A new type of appliance, introduced from the United States, and known as the edgewise arch, was shown by Mr. J. J. Tittle. It is obviously a useful method of dealing with certain types of malocclusion, but its capabilities cannot be properly assessed for a year or two, since it has been in use in this country for only a few months.

Excellent and technically beautiful radiographs of the temporomandibular joint were shown by Dr. S. Blackman, director of the X-ray department. These pictures, which reveal the true shape of the condylar head and give an accurate anteroposterior view of the ascending ramus, were taken by his new technique, details of which are to be published shortly. It is hoped that the already well-equipped department will soon be provided with the apparatus necessary for tomography.

Dr. J. E. Garside presented the results of an investigation into the cutting hardness of stainless-steel dental chisels. His results are interesting because they support the opinion of many dental surgeons that carbon steel is harder and more resistant to abrasion than the stainless variety.

During the morning session, demonstrations of oral surgery under general anæsthesia were given by Mr. M. P. Graham at the hospital's inpatient unit in the Grove Hospital, Tooting. Further clinical cases were shown in all departments during the afternoon session, which ended with the ever-popular brains trust, now in its third year. The team consisted of Mr. B. W. Fickling, Dr. A. B. MacGregor, Mr. H. M. Pickard, and Mr. W. E. Earle, under the chairmanship of Mr. N. J. Ainsworth. As in previous years, the questions with which they had to cope extemporaneously ranged from the slightly frivolous to the completely serious—from a question on whether parents should be warned of the high marriage-rate among women dental students to one on maintaining the high standard of dental teaching. As before, too, the team took these diverse matters in their stride, and provided an entertaining hour in which wit was nicely blended with many sound and useful opinions.

POLTERGEIST AND ZEITGEIST

Poltergeist phenomena, those ebullitions of china-smashing, stone-throwing, arson, and other extravagances, while so far remaining inexplicable on the physical plane, are beginning to make some kind of psychological sense. In a new book,[1] Mr. Hereward Carrington summarises the history of the poltergeist through the ages, and Mr. Nandor Fodor reviews some actual cases in the light of modern psychology. These phenomena, it has long been recognised, are usually associated with the presence of an adolescent child in the house; and the behaviour of the supposed spirit has much in common with that of an aggressive adolescent. On occasions, moreover, the ghost provides itself with a voice; and its conversation —as reported in the case of the "Bell witch," who in 1817 terrorised a family in Tennessee, or the "Saragossa ghost," who talked down a Spanish stove-pipe in 1934—is apt, like that of some young delinquents, to be abusive and grandiloquent. In short, supposing a disturbed adolescent with some form of hysterical dissociation were able—without direct physical contact—to wreak changes on his environment, these are very much the kind of changes he might wreak. The fact that poltergeist phenomena usually disappear as the associated young person matures lends additional colour to the theory.

A natural corollary would be to suppose that ghosts in general have a like origin; and this possibility led Mr. Fodor (who was formerly a psychical researcher and is now a psychoanalyst) to treat a lady whose house was haunted not for her ghost but for her complexes—with excellent results. Neither she nor the friend who shared the house was troubled by further visitations. This promising line of treatment suggests that in time we may be able to dispose of hauntings altogether; but it would be a pity if they became extinct before we have discovered what source of energy such disturbed patients are able to release from within, or tap from without, in order to engineer physical events which are apparent to others. By transferring the subject from the realm of the occult to the relatively respectable field of abnormal psychology Mr. Fodor may well have relieved investigators of some of the embarrassment which has so far hindered inquiry in this field.

University of Oxford

On April 30 the following degrees were conferred:

D.M.—J. V. Garrett, J. M. Jefferson.
B.M.—W. H. Allchin.

University of Cambridge

On April 25 the following degrees were conferred:

M.Chir.—P. G. Somerville.
M.B., B.Chir.—*E. J. Stacey.

* By proxy.

University of Leeds

Prof. Sydney Sunderland, professor of anatomy in the University of Melbourne, will give a lecture at Leeds General Infirmary, on Friday, June 12, at 8.15 P.M. He will speak on the Applied Anatomy of Peripheral Nerve Trunks.

Royal College of Physicians of Edinburgh

Queen Elizabeth, the Queen Mother, has accepted the honorary fellowship of the college.

At a meeting of the college held on May 5, with Dr. W. A. Alexander, the president, in the chair, the following were elected to the membership:

D. S. Nand, G. R. B. Kumarakulasinghe, W. MacLeod, S. N. Wanchoo, L. K. Ganguli, W. D. L. Fernando, N. Y. McCallum, E. W. Moore, M. Hasan, R. A. Gulmohamed, I. F. Sutherland, D. A. I. Grewar, B. Senior, N. Feldman, Y. Ho, Q. G. Quah, S. K. Biswas, W. S. A. Allan, T. H. Maniar, K. Z. Hasan, M. M. Baig, W. L. F. Hatchuel, A. Sandler, I. N. Marks, A. T. Lambie, J. K. McKechnie, C. Nwokolo.

Institute of Child Health, London

Three guest lectures are to be given at the institute at The Hospital for Sick Children, Great Ormond Street, W.C.1. On Thursday, May 28, Prof. S. van Creveld (Amsterdam) will speak on the Clinical Significance of New Clotting Factors; on Thursday, June 25, Dr. W. C. Davison (Duke University, N. Carolina), on Childhood Cancer; and on Thursday, July 2, Prof. G. Fanconi (Zürich), on Renal Dwarfism. All the lectures are at 5 P.M., and admission is free.

Education for Parenthood

The National Association for Maternity and Child Welfare has chosen this subject for discussion at its annual conference, to be held at St. Pancras Town Hall, Euston Road, London, N.W.1, on June 10, 11, and 12. The speakers will include Dr. Jean Mackintosh, Dr. John Burton, and Dr. Catherine B. Crane. Tickets (21*s.*) may be had from the secretary, N.A.M.C.W., Tavistock House North, W.C.1.

Workmen's Compensation and Sickness Benefit

From May 7 totally disabled persons receiving Workmen's Compensation are no longer to have their sickness benefit reduced on that account. The regulations making this change have been made by the National Insurance Joint Authority with the approval of the National Insurance Advisory Committee. (S.I. 1953. No. 765. H.M. Stationery Office. 2*d.*)

Harveian Society of London

This society's Buckston Browne—Gray Hill dinner was held at the Royal College of Surgeons on May 6. The Dean of St. Albans, proposing The Society, declared that custom outlives rule; and he urged members to keep the society alive for the future, which, judging by present signs, would see a spiritual revival and renewed initiative. In his reply, Dr. Tom Hare, the president, said that Sir Buckston Browne always spoke with pride of the address he gave to the society on his method of crushing stone. The President extended a special welcome to Dr. G. F. Abercrombie, chairman of the foundation council of the College of General Practitioners. Dr. D. A. Imrie spoke generously of the guests. Mr. Justice Danckwerts, in his response, remarked that Harvey's work on the circulation occupied 52 pages; and he commended this example of brevity to modern scientists. Dr. Abercrombie reported that the support for the new college was very gratifying.

[1] The Story of the Poltergeist down the Centuries. London: Rider. 1953. Pp. 216. 16*s.*

probably because the increase in size is the end result of rheumatic myocarditis rather than simple hypertrophy due to work They are found in those with relatively little enlargement but with clinical and electrocardiographic evidence of right ventricular hypertrophy In a few there has been no radiological evidence of enlargement of the heart Patients in this group tend to die young from "pulmonary failure"—i e , severe congestion and œdema, often with infarction

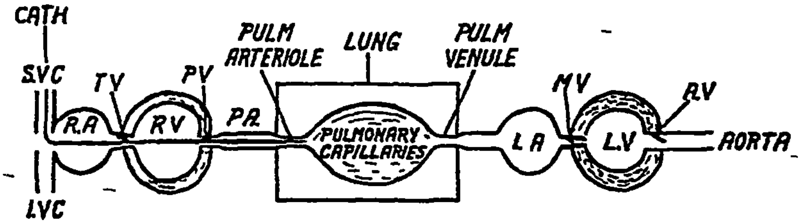

Fig 5—Position of cardiac catheter recording pulmonary capillary venous pressure When catheter tip is withdrawn into main pulmonary artery, pressure rises by resistance of pulmonary arterioles A V, aortic valve Cath, catheter, I V C, inferior vena cava, L.A, left atrium L.V, left ventricle M V, mitral valve P A, pulmonary valve, R.A right atrium, R V, right ventricle, S V C, superior vena cava, T V tricuspid valve

We have found that the degree of pulmonary hypertension cannot always be determined even approximately except by cardiac catheterisation There may be a striking discrepancy between the pulmonary arterial pressure recorded by the manometer and that deduced from the loudness of the pulmonary second sound or from the size of the pulmonary arterial shadow Although it is true that, when the pulmonary second sound is very loud or the pulmonary artery is much enlarged, pulmonary hypertension is usually considerable, the converse does not hold

Analysis of the cases of 24 patients with the highest pressures, excluding 2 who were pregnant, shows that all were severely disabled by dyspnœa on exertion and were liable to breathless attacks on slipping down in bed, but none had experienced an attack of acute pulmonary œdema All 12 patients in whom pulmonary capillary-venous pressures were recorded had evidence of considerable pulmonary arteriolar resistance This increased pulmonary resistance may explain why 20 of the 24 patients had electrocardiographic evidence of right ventricular hypertrophy All had tight mitral stenosis Only 5 had established auricular fibrillation, and they were aged more than forty One man, aged thirty-four, had an episode of fibrillation shortly before operation following catheterisation 15 gave a history of hæmoptysis

The increased pressure in the pulmonary artery in patients with mitral stenosis is due partly to the resistance at the narrow mitral valve, and partly to that in the pulmonary arterioles, which are narrowed by intimal proliferation and medial hypertrophy It is probable, although unproved, that arteriolar resistance may also be affected by vasoconstriction If the mitral valve is narrowed, the blood-flow can be maintained or increased on exertion only by a rise of pressure in the left atrium Since there are no valves between the mitral valve and the pulmonary capillaries, pulmonary hypertension results Narrowing of the pulmonary arterioles (fig 5) may be regarded as a protective phenomenon in that it tends to reduce the blood flow from the right ventricle, and so to prevent the lungs from being flooded On the other hand, an increase in pulmonary arteriolar resistance increases the work of the right ventricle, and will contribute to its eventual failure It will be appreciated that the patients with mitral stenosis who are in danger of pulmonary œdema are those with tight mitral stenosis, relatively little pulmonary arteriolar resistance, and a strong right ventricle The symptoms of mitral stenosis are those of pulmonary hypertension and reduced blood-flow, the first causing dyspnœa on exertion, orthopnœa, paroxysmal dyspnœa, and hæmoptysis, and the second weakness, fatigue, and lassitude

The opinion has been expressed that very high pressures are a contra indication to operation on the grounds that they show irreversible changes in the pulmonary arterial tree Our results in this particular group have been most encouraging, and a regression of electrocardiographic evidence of right ventricular hypertrophy suggests that the changes resulting from severe stenosis are not in all cases irreversible (fig 4) Soon after valvulotomy much or little improvement may be noted, but in either case gradual improvement may continue over many months Initial improvement is tentatively ascribed to the relief of valvular obstruction, and the later gradual improvement to regression of the arteriolar changes

The limitations of pressure recordings without calculation of blood flow are appreciated, but in most of the cases in which the pressures were relatively low mitral stenosis was not very severe—i e , the valve would just admit the terminal phalanx of the index finger On the other hand, a relatively low pulmonary arterial pressure may be due to severe myocarditis affecting the right ventricle Case 94 is a good example of this

A girl, aged twenty five, had, on arrival from a long journey, congestive cardiac failure with gross œdema and ascites and a large heart (cardiothoracic ratio 68%) She responded well

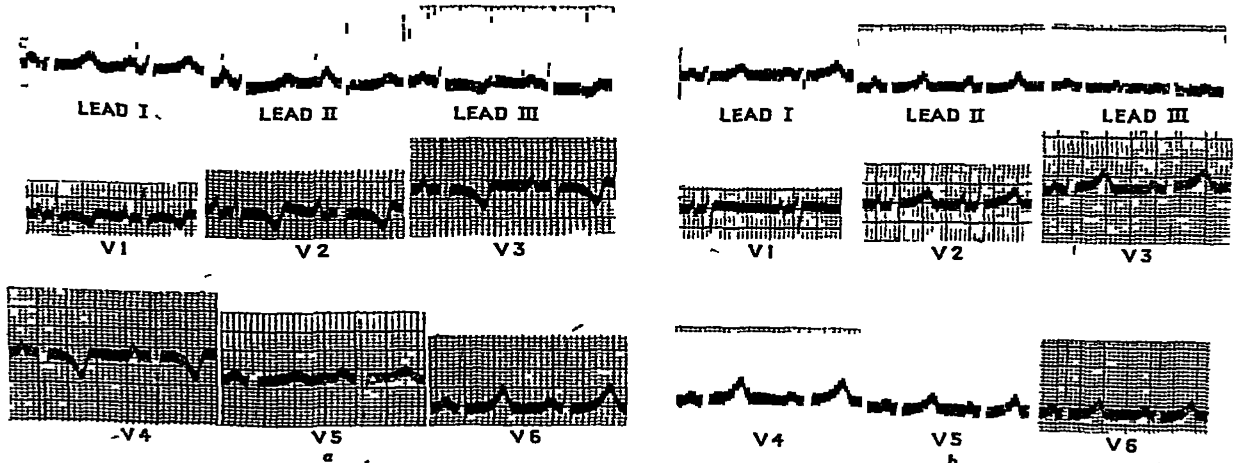

Fig 4—Electrocardiograms a pattern of right ventricular hypertrophy (tall R waves and negative T-waves in leads recorded over right ventricle), b recession of signs of right ventricular hypertrophy in same patient sixteen months after valvulotomy

American Otological Society

The 1953 award of merit and gold medal of this society has been presented to Dr. Julius Lempert.

Royal Medical Benevolent Fund

The annual general meeting of the Fund will be held on Tuesday, June 9, at 5 P.M. at 11, Chandos Street, London, W.1, with Lord Webb-Johnson, the president, in the chair.

Liverpool Medical Exhibition

At 11.30 A.M. on Monday, May 18, Dr. E. N. Chamberlain will open this exhibition at St. George's Hall, Liverpool. It will be open daily from 11 A.M. to 6.30 P.M. till May 22.

British Association for the Advancement of Science

Sir Henry Dale, O.M., F.R.S., will take the chair at a meeting of this association on Thursday, May 28, at 6 P.M., at the Royal Institution, Albemarle Street, London, W.1, when Sir Harold Hartley, F.R.S., will deliver the Alexander Pedler lecture on the Life and Times of Sir Richard Gregory.

British Association of Sport and Medicine

At a meeting of this association at the Westminster Hospital Medical School, Horseferry Road, London, S.W.1, on June 24, at 5 P.M., Sir Adolphe Abrahams and Dr. A. McEldowney will open a discussion on the Doping of Athletes.

R.A.F. Appointments

Air Vice-Marshal V. S. Ewing has been appointed principal medical officer, Home Command; and Air Commodore R. H. Stanbridge principal medical officer, Middle East Air Force, with the acting rank of air vice-marshal.

Health Exhibition at Deptford

An exhibition showing the work of the personal health services in Deptford, Greenwich, and Woolwich is to be held at the Health Centre, Amersham Road, Deptford, from noon to 6 P.M. on Friday, May 15, and from 10 A.M. to 6 P.M. on Saturday, May 16.

International Scientific Film Association

The seventh congress of this association will be held in London from Sept. 18 to 27, in the National Film Theatre and Royal Festival Hall. Special meetings and film shows will be devoted to the technique and application of films in medicine. Further particulars may be had from Dr. R. C. Mac Keith, the vice-chairman of the medical committee, Guy's Hospital, London, S.E.1.

Anglo-French Exchange Bursaries

The following have been awarded bursaries for special studies in France:

F. B. COCKETT, senior lecturer, professorial surgical unit, St. Thomas's Hospital, London.

R. H. GORRILL, senior lecturer in bacteriology, University of London.

A. MACDONALD, reader in bacteriology, University of Liverpool.

A. MCPHERSON, 1953 Laming-Evans research fellow of the Royal College of Surgeons.

J. W. F. SCRIMGEOUR, senior registrar in obstetrics and gynæcology at St. Mary's Hospital and Crumpsall Hospital, Manchester.

E. C. TURTON, consultant psychiatric physician in charge of the department of electro-encephalography and electrophysiology, Barrow Hospital, near Bristol; tutor in electro-encephalography, University of Bristol.

Society of Chiropodists

The annual dinner of this society was held at the Park Lane Hotel on May 7. Responding to Sir Henry Souttar's toast of The Society, Mr. J. H. Hanby, the president, said that the prevention of foot disabilities came first in the society's programme, and the regular inspection of school-children's feet was one of the most important preventive measures. The seriousness of the matter was shown by the high proportion —about 70%—of the community who had abnormal feet. To enable the public to know where it could obtain scientific chiropodial treatment, a State register of chiropodists was essential, and the society would continue to urge the Government to establish one. Mr. S. Coates, vice-president of the society, welcomed the guests, among whom were Lord Webb-Johnson, Lord Hollenden, Sir Cecil Wakeley, Sir Heneage Ogilvie, Sir Harry Platt, and Sir Zachary Cope. In his reply, Sir Zachary commended the society for insisting on a State register, and he hoped that the combined efforts of all the medical auxiliaries would shortly induce the Government to act.

Prof. C. A. Wells has spent a week in Syria lecturing for the British Council. He is on his way to Hong-Kong to act as external examiner at the university.

Diary of the Week

MAY 17 TO 23

Monday, 18th

UNIVERSITY COLLEGE, Gower Street, W.C.1
4.45 P.M. Sir Rudolph Peters, F.R.S.: Inhibitors and Intracellul Chemical Dissection. (Last of four lectures.)
POSTGRADUATE MEDICAL SCHOOL OF LONDON, Ducane Road, W.1
4 P.M. Prof. R. V. Christie: Dyspnœa.
MANCHESTER MEDICAL SOCIETY
9 P.M. (University of Manchester.) *Section of General Practic* Dr. R. H. Titcombe: The General Practitioner and Pos graduate Education. (Presidential address.)

Tuesday, 19th

NEWSHOLME LECTURE
5.15 P.M. (London School of Hygiene and Tropical Medicin Keppel Street, W.C.1.) Prof. Alan Moncrieff: Chil Health and the State—Infant Welfare and the Ministry Health. (First of three lectures.)
INSTITUTE OF DERMATOLOGY, St. John's Hospital, Lisle Stree W.C.2
5.30 P.M. Dr. S. C. Gold: Lupus Erythematosus.
WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY, St. Mary's Hospita Medical School, W.2
5 P.M. Brigadier J. S. K. Boyd, F.R.S.: Bacteriophage Typin and Epidemiology. (Almroth Wright lecture.)
SOUTH WEST LONDON MEDICAL SOCIETY
8.30 P.M. (Bolingbroke Hospital, Wandsworth Common, S.W.11. Dr. Benjamin Barling: Diseases of the Thyroid.
UNIVERSITY OF ST. ANDREWS
5 P.M. (Medical School, Small's Wynd, Dundee.) Dr. C. G. Kin (New York): *Aspects of Nutrition.*

Wednesday, 20th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
6.30 P.M. Prof. A. M. Boyd: Dextran—The New Narrow Fractio (First showing of the film.)
POSTGRADUATE MEDICAL SCHOOL OF LONDON
2 P.M. Dr. F. O. MacCallum: Laboratory Diagnosis of Viru Diseases.
ROYAL SOCIETY OF MEDICINE
5 P.M. *Section of Comparative Medicine.* Sir William Ogg, PH.D., Mr. G. C. Ainsworth, PH.D., Dr. D. P. Cuthbertson, Sir James Scott-Watson, D.SC.: Organic Manures and Fertilisers and Production and Composition of Food for Man and Animals.
8 P.M. *Section of General Practice.* Mr. Melford Stevenson, Q.C.: The Medical Witness.
NEWSHOLME LECTURE
5.15 P.M. (London School of Hygiene and Tropical Medicine.) Professor Moncrieff: School Health and the Ministry of Education. (Second of three lectures.)
INSTITUTE OF DERMATOLOGY
5.30 P.M. Dr. J. O. Oliver: Pathology of Lupus Erythematosus.
MIDDLESEX HOSPITAL MEDICAL SCHOOL, W.1
4.30 P.M. Prof. E. C. Dodds, F.R.S.: Chemicals and Food—A Reconsideration. (Sanderson-Wells lecture.)
ROYAL COLLEGE OF SURGEONS OF EDINBURGH, 18, Nicolson Street, Edinburgh, 8
3.30 P.M. Dr. R. B. Cattell (Boston): Carcinoma of the Pancreas.

Thurday, 21st

POSTGRADUATE MEDICAL SCHOOL OF LONDON
4 P.M. Dr. E. S. Clarke: Cerebral Circulation.
NEWSHOLME LECTURE
5.15 P.M. (London School of Hygiene and Tropical Medicine.) Professor Moncrieff: The Deprived Child and the Home Office. (Last of three lectures.)
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 26, Portland Place, W.1
7.30 P.M. Dr. J. C. Broom: Leptospirosis in Tropical Countries.
LONDON JEWISH HOSPITAL MEDICAL SOCIETY
8.30 P.M. (11, Chandos Street, W.1.) Prof. David Slome: Experimental Surgery.
SOCIETY FOR ENDOCRINOLOGY
9.30 A.M. (11, Chandos Street, W.1.) Symposium on the Determination of Adrenal Cortical Steroids and their Metabolites.
NORTH-WESTERN TUBERCULOSIS SOCIETY
5 P.M. (Manchester Royal Infirmary.) Dr. W. Robinson: Air Cysts of Lung. Dr. G. Penrhyn Jones: Pulmonary Adenomatosis.
HONYMAN GILLESPIE LECTURE
5 P.M. (University New Buildings, Teviot Place, Edinburgh.) Dr. M. W. Paterson: Abnormalities of Optic Disc.
UNIVERSITY OF ST. ANDREWS
5 P.M. Prof. Harold Scarborough: Purpura.

Friday, 22nd

POSTGRADUATE MEDICAL SCHOOL OF LONDON
2 P.M. Mr. F. Masina: Diagnosis and Surgery of Bladder Tumours.
4 P.M. Dr. B. M. Wright: Inhalation and Retention of Aerosols.
INSTITUTE OF DERMATOLOGY
5.30 P.M. Dr. W. N. Goldsmith: Xanthoma, Necrobiosis Lipoidica and Granuloma Annulare.
INSTITUTE OF OBSTETRICS AND [illegible] W.6.)
2 P.M. (Queen Charlotte's [illegible] is in Dr. J. Purdon Marti [illegible] Pregnancy and Puerperium.

The fifth and latest issue of *Prescribers' Notes* has now been sent to executive councils for distribution to doctors taking part in the National Health Service. Hospital boards are invited to apply for copies for members of their medical and pharmaceutical staffs.

to treatment. Her mean pulmonary arterial pressure was 26 mm Hg (systolic pressure 38 mm Hg, right ventricular filling pressure 5 mm Hg). She had tight stenosis.

Cardiac Failure

It might be thought easy to decide whether or not a patient has cardiac failure, but in practice, for lack of a simple clinical definition, it may be difficult. The customary objective criteria include crepitations at the bases of the lungs, peripheral œdema, distended neck veins, and enlargement of the liver, and when these are present the diagnosis is clear. Judged by symptoms (dyspnœa, pulmonary œdema, hæmoptysis, tiredness, and weakness) the heart may fail to provide an adequate output for the needs of the body, although the above-mentioned signs are absent. To ascertain whether cardiac failure has occurred in the past is still more difficult. A history of œdema of the ankles is common in women, especially if their day includes much standing; it often comes on during pregnancy. This œdema is mistaken for cardiac œdema, even when the heart is healthy; and if the heart is known to be diseased the inference is harder to avoid. A single sign, such as œdema, occurring without supporting evidence requires critical interpretation.

In the assessment of the severity of rheumatic heart-disease, cardiac failure occurring once at the onset of auricular fibrillation should be distinguished from cardiac failure occurring otherwise. The sudden change of rate and rhythm imposes a severe strain on the heart; but, if initial treatment is adequate and digitalisation is maintained, failure may not recur for many years.

Every effort should be made to secure freedom from cardiac failure before deciding on operation. In some patients this is impossible because their disease has progressed too far and the myocardium is severely damaged. Others have tight mitral stenosis and yet little enlargement of the heart, because the myocardium has not been injured by the rheumatic process and has responded by simple hypertrophy. They usually have normal rhythm, gross pulmonary hypertension, and electrocardiographic evidence of right ventricular hypertrophy. Pulmonary congestion is severe. The size of the mitral orifice is insufficient to permit an adequate cardiac output even under basal conditions. Valvulotomy may be followed by early relief of symptoms and later regression of the signs of ventricular hypertrophy. It is important to operate on this group of patients without delay, for they may become unfit for valvulotomy within a few months because of progressive cardiac failure or pulmonary infarction from thrombosis in the pulmonary arteries.

POSTOPERATIVE CARDIAC FAILURE

30 patients in this series developed signs of congestive cardiac failure within two weeks of operation and before being allowed out of bed. No patient developed failure after being allowed up. Cardiac failure in those in whom operation is believed to carry a serious risk was not surprising, but sometimes it occurred unexpectedly in patients who had never previously experienced it. In no case was it severe, and in most it amounted to no more than slight peripheral œdema or congestion of the neck veins. The few in whom treatment was considered necessary responded to the customary measures of restriction of salt intake, injections of mercurial diuretics, and digitalis. 5 patients experienced a mild attack of cardiac failure after returning home. In 2 this could be attributed to giving up digitalis prematurely, and in 2 to an attack of rheumatic fever. One (case 2) was a patient whose condition was not materially influenced by operation.

Pregnancy and Mitral Stenosis

We shall not discuss here the way in which pregnancy may aggravate mitral stenosis, or the general management of mitral stenosis in pregnancy except in relation to valvulotomy.

It is usually stated that there is no evidence that pregnancy permanently aggravates rheumatic heart disease, but we have been impressed by the frequency with which patients date the onset of their symptoms or of material deterioration of their condition to pregnancy. This matter requires further study.

In pregnancy the blood volume increases by 25–40% between the third and eighth months, and this increase may explain the change in symptoms and signs which takes place in patients with mitral stenosis. The circulatory effects of moderately tight mitral stenosis in pregnant patients are similar to those of very tight stenosis in the non-pregnant. Undue breathlessness on effort and discomfort on lying flat may be appreciated for the first time or be greatly aggravated. Such symptoms may be evident within two or three weeks of the start of pregnancy. Paroxysmal dyspnœa, pulmonary œdema, and hæmoptysis are liable to occur in patients who previously were not materially disabled. Auscultatory signs which before pregnancy were hard to detect may be striking. Pregnancy might therefore be considered a good test of the severity of the underlying heart disease, but this may be fallacious. Even severe signs and symptoms may regress after the confinement, and the patient may remain well for several years.

Nevertheless during pregnancy, as early as the second or third month, symptoms may become severe enough to compel a choice between termination of the pregnancy, continued observation in hospital, and valvulotomy. Natural delivery at term is generally considered to carry less risk than termination of pregnancy after the fourth month. It sometimes happens that attacks of pulmonary œdema or hæmoptysis occur without a known precipitating factor and continue although the patient is kept at rest; and it is in such circumstances that valvulotomy should be considered. There is no reason to suppose that the risk of operation is increased in early pregnancy.

The cases of 2 patients in this series who were operated on during pregnancy as an alternative to termination have already been reported (Logan and Turner 1952a). They remained well throughout the ensuing months, and each was safely delivered of a healthy child at full term. A 3rd woman was observed during a severe attack of acute pulmonary œdema with hæmoptysis which took three days to resolve.

During treatment in hospital two less severe attacks of pulmonary œdema and further hæmoptysis occurred. There was no reason to suppose that these attacks would not continue and even, since the blood volume would further increase, become more severe. The resting pressure in the pulmonary artery was high (45 mm Hg), and accordingly valvulotomy was advised. At operation the lung was found to be heavy with œdema, and there was a hydrothorax of more than 300 ml. The mitral valve just admitted the terminal phalanx of the index finger, and the valvular orifice was satisfactorily enlarged.

We do not suggest that valvulotomy in pregnancy is often required. With few exceptions, patients in whom mitral disease complicates pregnancy can, by careful medical treatment, be safely carried to term, and whenever possible this is the better way.

(*To be concluded*)

> “But I have the hardihood to believe that there is little in the content of real science that cannot be made clear to the ordinary man *in* ordinary plain English. That technical terms and certain unfamiliar words must of necessity be introduced I freely admit; but that any man’s views on life—its modifications and even its meanings—cannot be transmitted in plain and familiar terms to his fellow men *I do not* believe.”—Prof. F. WOOD JONES, F.R.S. *Trends of Life.* London, 1953; p. 191.

MITRAL STENOSIS

DIAGNOSIS AND TREATMENT

ANDREW LOGAN
M.B. St. And., F.R.C.S., F.R.C.S.E.
LECTURER IN THORACIC SURGERY, UNIVERSITY OF EDINBURGH ;
THORACIC SURGEON, SOUTH EAST SCOTLAND REGION

RICHARD TURNER
O.B.E., M.A., M.D. Camb., F.R.C.P., F.R.C.P.E.
SENIOR LECTURER IN MEDICINE, UNIVERSITY OF EDINBURGH ;
PHYSICIAN, WESTERN GENERAL HOSPITAL, EDINBURGH

SURGICAL treatment has brought new life and new hope to many who were incapacitated, in varying degree, by mitral stenosis. Valvulotomy provides an illuminating method of investigation as well as effective treatment and has given impetus to the study of the natural history of the disease.

Not long ago most physicians were content merely to make a diagnosis of mitral stenosis. Cardiologists then began to differentiate certain groups of patients, for example, the "œdematous" group of Gallavardin (1934), which corresponds to the patients described below who have tight stenosis, little cardiac enlargement, normal rhythm, and attacks of paroxysmal dyspnœa. Today it is important to assess in each case not only the degree of mitral stenosis but also the state of the myocardium and lung, the resistance in the pulmonary arterioles, the degree of mitral incompetence and aortic valvular disease, if present, and the rate of progression of the disability. The surgeon can improve only the degree of mitral stenosis, and occasionally perhaps the valvular action of the mitral cusps. Now that precision in diagnosis is important, and the clinical assessment can be confirmed or confounded at operation, it is desirable for clinicians to re-examine their present views in the light of the findings at operation.

The experience of only one other hospital has so far been reported from this country (Baker et al. 1950, 1952). Since experience everywhere is limited, we decided not to review published work but merely to describe our own.

MATERIAL

Of 200 patients subjected in the past two and a quarter years to thoracotomy for mitral valvular disease 130 came from one medical unit. This paper is principally concerned with the study of the first 100 of these 130, who had pure or predominant mitral stenosis for which valvulotomy was performed (table I). Of the remainder 17 had predominant mitral incompetence, and 16 of these were treated by a different operation ; 11 have already been reported (Logan and Turner 1952b).

TABLE I—AGE, SEX, AND CARDIAC RHYTHM

Age (yr.)	Total no. of patients	Male	Female	Auricular fibrillation
10–19	1	0	1	0
20–29	22	2	20	7
30–39	36	7	29	9
40–49	27	4	23	17
50–59	14	4	10	7
Total	100	17	83	40

Early in our experience 2 patients were found at operation to have predominant mitral incompetence although this had not been suspected preoperatively. One patient had a thoracotomy only, because the auricle was found to be vestigial and too small to admit the surgeon's finger. One had her valvulotomy repeated later because of unsatisfactory progress.

Except when otherwise stated, all the statistics cited refer to the 100 patients with predominant stenosis.

Each patient was studied in detail, and there was seldom a case which did not present some new facet of the diagnosis or treatment of mitral disease, or provide information of value for the future. Most of the patients stood the operation well, made a satisfactory convalescence, although not without occasional incident, and returned home well pleased.

The group of patients is representative of the whole range of mitral stenosis, except for mild lesions not known to be progressive, and those with large hearts and uncontrollable cardiac failure. Ages varied from sixteen to fifty-nine. More than a third had auricular fibrillation, and almost a third had experienced cardiac failure. Many gave a history of pulmonary œdema or of hæmoptysis. Many had large hearts. If it was believed that improvement could be obtained, patients were accepted in spite of considerable operative risk, since the only alternative was rest, further restrictions, and digitalis, without prospect of sustained symptomatic relief.

Symptoms

Mitral stenosis is recognised primarily by the auscultatory findings, but these do not indicate the degree of stenosis or the severity of the functional incapacity. Attention must be paid to the history, a detailed clinical examination, and an analysis of the radiological and electrocardiographic findings. In addition useful information may be obtained by cardiac catheterisation, although in many cases this is not essential.

We shall consider here chiefly those features which are important in the assessment for operation.

DYSPNŒA

It would not seem difficult to ascertain how breathless a patient is ; but *dyspnœa on exertion* may be purely subjective, and patients vary widely in their appreciation of its severity. In the absence of special apparatus the degree of dyspnœa may be roughly assessed by accompanying the patients up one or more flights of stairs. Some belittle what is, to the observer, clearly a considerable disability, and others make much of a slight limitation of their activity. Especially in young people there is danger of attaching too little importance to a complaint of dyspnœa, since tight mitral stenosis and pulmonary hypertension may be present although the heart is of normal size and there is no manifest congestion of the lungs at the time of examination. In such cases data obtained by cardiac catheterisation may be of value.

Dyspnœa which is progressive is an indication for considering operation.

Orthopnœa

Orthopnœa is a sign of severe pulmonary congestion, and therefore either of tight mitral stenosis or of severe myocardial damage. If the myocardium is much damaged, the heart is usually much enlarged.

Acute Paroxysmal Dyspnœa

Patients with mitral stenosis often suffer from acute paroxysmal dyspnœa. The attacks are unpredictable, and there may be long intervals between episodes of great severity. Why they occur in some patients and not in others who have a similar degree of mitral stenosis is unknown, but one factor is probably the degree of pulmonary arteriolar resistance (see below). During the attack the pulse-rate is usually rapid, and the pounding of the heart may be seen through the clothes and heard several feet away. In a sense the attacks are due to left atrial failure—i.e., they are precipitated by any factor which temporarily increases the cardiac output with the result that the right ventricle pumps into the lungs more blood than the left atrium can accommodate and pass on to the left ventricle. As a result severe congestion of the lungs develops.

TROUBLESOME TAPEWORMS

RICHARD ASHER
M D Lond, F R C P

PHYSICIAN, CENTRAL MIDDLESEX HOSPITAL, LONDON

THE title is chosen deliberately to emphasise that apeworms are troublesome, both because they cause ymptoms and because they can be difficult to treat apeworms in this country are often considered as a oke, and regarded as more suitable for examination uestions than *for consideration of their clinical* importance I have not been able to find any article on beef apeworms published in British medical literature in he last ten years

Since 1943, in the routine practice of a general hysician, I have seen thirteen patients with the beef apeworm (*Tænia saginata*), which shows that such nfestation is not a great rarity Of these thirteen atients six complained of general symptoms before hey noticed they were passing segments, and in some ases these symptoms were severe In a case of obscure bdominal pain the diagnosis of tapeworm is worth onsidering Tæniasis, though certainly not a common ause of abdominal pain, is probably as important as orphyria, tabetic crisis, Addison's disease, and other are but well-known causes of abdominal pain

CASE-RECORDS

The following case records illustrate the symptoms that beef tapeworm can cause

Case 1 —A hospital sister, aged [illegible], began in 1942 to have attacks of colicky central abdominal pain in bouts lasting 2 or 3 days At first there were intervals of about a week with no pain, but after 6 months the pain became more frequent and more severe till it occurred almost daily At that time she noticed that her appetite was increased, and particularly at midday or last thing at night she had a sudden craving for food which, when satisfied, considerably improved her abdominal pain After 9 months she began to vomit two or three times a week about 2 hours after food, this made the pain worse, and she began to feel "really rotten" (as she put it), though normally she was a most cheerful and active person

10 months after her first symptoms she was diagnosed as having chronic appendicitis and operated on, but, though the appendix was reported as chronically inflamed, her pain and vomiting persisted unchanged after its removal A fortnight after the operation she happened by a lucky chance to look at her motions and saw moving white segments At that time she was severely incapacitated by her pain, she had lost 1½ st in weight, and could hardly carry on her nursing duties After routine treatment the complete worm was found, and all her symptoms disappeared next day She has been perfectly well ever since

She admitted that since she had been given bits of raw meat "to play at shops with" as a child she had acquired a taste for it, and that she regularly used to eat raw meat

Case 2 —A housewife of 34 was admitted in 1949 For 9 months she had mild indigestion, and 8 months before admission she had been in bed for a fortnight with "gastric flu" characterised by severe sickness whenever she got out of bed, and diarrhœa For 2 months she had felt worried and miserable She had severe colicky "rolling" pains worse in the mornings, and slightly eased by her midday meal Sometimes these pains were so severe that when doing her housework she would have to stop sweeping hold on to her broom, and groan aloud Her friends noticed that she looked ill and pale, and she lost enough flesh for her to have to alter the buttons on her stays and her skirt The pain continued unabated till her admission Though her appetite became rather poor throughout this illness, she used to get sudden bouts of hunger, particularly in the evenings

8 months after the *onset of* her *symptoms* she noticed "small white pieces which moved" in her motions She took some worm powders that her chemist gave her and then passed several feet of worm, but the symptoms and the passage of segments continued till she was referred to hospital for treatment After routine treatment the whole worm was recovered, and her symptoms disappeared straight way and have not returned She told us that she often ate beef sausages completely raw

Case 3 —A Lebanese nurse, aged 25, was admitted in 1952 with a month's history of increased appetite, giddy feelings, and central abdominal cramps The hunger was worse in the mornings, but she couldn't eat as much as her appetite was asking ' The abdominal pain came in short attacks lasting 2 seconds but was severe while it lasted The giddiness was bad enough to make her feel very unsteady when she first got out of bed in the morning A fortnight later she noticed that segments came out from the anus even when she was not defæcating she inspected her motions and noticed more She was admitted 2 weeks later After routine treatment the whole worm was recovered, all her symptoms ceased forthwith, and she has remained completely well

She said that her people (the Lebanese) habitually eat all their meat raw, and she had recently been on holiday in Lebanon eating raw meat

ANALYSIS OF THE THIRTEEN CASES

Of the nine patients who were asked, eight admitted to eating raw meat, so this appears to be an important factor

There were eight women and five men No children were affected Four of the patients had received previous courses of treatment elsewhere, and the worm had grown again One of these patients, a man of 40, had had sixteen ineffective courses of treatment, the other patients had received from one to four courses All the cases were cured the head of the worm being found and identified in twelve cases and in the remaining patient, though the head was missed, a clinical follow-up 5 months later established that there was no recurrence Infestation varied from 5 days to 6 years, but the commonest length of infestation was about 6 months

DIAGNOSIS

Tapeworm is rarely diagnosed before the patient notices segments, but in cases of obscure colicky abdominal pain, with bouts of unexplained hunger or giddiness, it is worth *asking the patient to inspect the motions* When segments are present they are easily seen, for the mature proglottides are a distinct whitish yellow colour, and they move, changing their shape from ▭ to ▯. Affected patients have told me that they never pass more than three motions without seeing segments, and these are usually present in every motion Sometimes segments migrate from the anus spontaneously, this is pathognomonic of *T saginata* and does not happen with *T solium* Often a patient says he has a tapeworm when he has roundworms or threadworms, and it is wise to ask the patient to draw rough pictures of the alleged segments or, better still, to bring up some for laboratory examination, so that he is not admitted for a course of treatment until it is certain he has a tape worm Patients may have had previous inadequate courses of treatment followed by the passage of several feet of the worm which makes the diagnosis certain on the history alone

TYPES OF WORM

In this country if a patient has a tapeworm it is almost certain to be a beef tapeworm. There are however, three possible infestations—by beef tapeworm, by pork tapeworm, and by fish tapeworm As the treatment for these is the same, it is of academic interest to decide which worm is present before treatment

Microscopy of the proglottides or of the ova can settle the matter, and there are also clinical differences The beef tapeworm is more likely to produce clinical symptoms, such as abdominal pain, hunger, and giddiness and the proglottides often migrate from the anus independent of defæcation The pork tapeworm rarely produces clinical symptoms, and its proglottides rarely migrate from the anus In England it is much rarer than the

TABLE II—ANALYSIS OF CASES

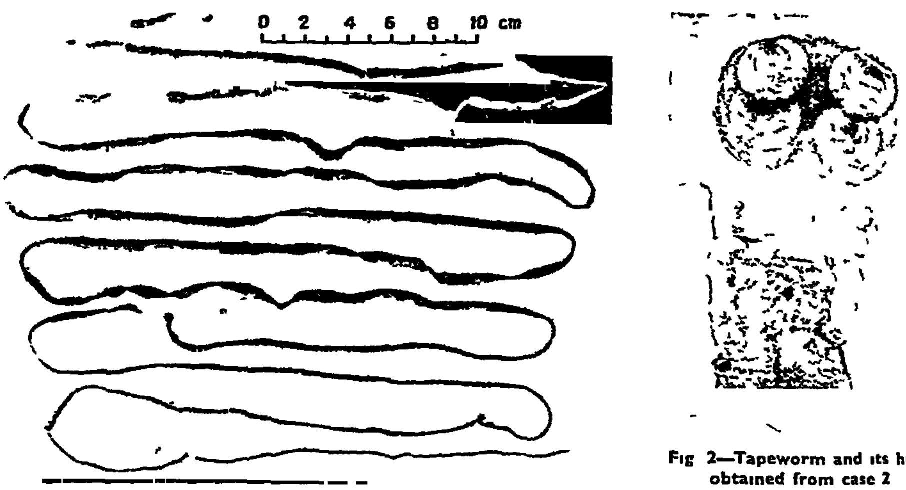

Fig 2—Tapeworm and its head obtained from case 2

beef tapeworm, but it is a much more dangerous parasite, because the host can infect himself (or others) with the cystic stage of the parasite if the ova he passes reach the mouth (via food, fingers, or flies) This general cysticercosis may cause only muscular pains and fatigue if confined to the muscles, but if it involves brain or eyes it may cause fits, mental deterioration, or blindness (Dixon and Hargreaves 1944) Fig 1 shows numerous cysticerci in muscles from a patient with cerebral cysticercosis

The fish tapeworm is very rare in this country and occurs mostly around the Baltic, near the freshwater lakes of Europe It has a complicated life-cycle, passing through a one eyed water-flea and a fish, and sometimes causes an anæmia resembling pernicious anæmia, by interfering with the reaction between extrinsic and intrinsic factors Harland et al (1950) reported a case in this country in a Finnish servant

LIFE-CYCLE OF BEEF TAPEWORM

Man is the only definitive host for the beef tapeworm, and the cow the only intermediate host Therefore it is astonishing that the cycle persists, for, to acquire cysticercus bovis, a cow has to eat grass contaminated by the fæces of a tapeworm-infected man, and this cow has to be eaten partly raw by another man—whose fæces must then reach a cow-inhabited field if the cycle is to continue It might have been thought that with modern sanitation and cooking the parasite would become extinct in this country, but it is certainly not becoming less common The 13 cases I report here are distributed in the last ten years as follows

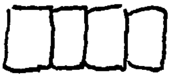
1943–48	4 cases
1948–52	9 cases

TREATMENT

A standard course of treatment was used in all these cases as follows

Preparation—The patient is admitted to hospital and kept on an entirely fluid diet for 3 days On each of these days he is given mist alba $^1/_2$ oz in the morning and mist cascaræ $^1/_2$ oz in the evening The purpose of this is to make the fæces completely fluid, so that the passing of the worm and the finding of the head shall be easier If the motions are not sufficiently liquid by the 3rd day, the dose of mist alba and mist cascaræ should be doubled, and an enema given in the evening

Day of Treatment—On the 4th day the patient is allowed nothing by mouth apart from the medicines At 7 A M he is given 1 oz of mist alba, and at 8 A M he starts taking capsules of 15 minims of male fern every quarter of an hour for eight doses At 11 A M a warm saline enema is given The worm will probably come away with the result, if not another enema should be given an hour later The nurses are firmly instructed that no motions are to be thrown away until the head has been found and its authenticity confirmed by the doctor They are also shown a drawing of the size of the head • and of the segments near it to show their extreme smallness compared with the mature segments



It is wise to award half a crown to the finder of the head With the naked eye one can be reasonably certain of it, but confirmation is easily obtained with a pocket magnifying glass or an auriscope without its speculum Fig 2 shows the worm and its head obtained from case 2

RESULTS

Twelve patients were cured at the first attempt with the standard course just described The remaining patient had harboured his worm for 6 years and received sixteen previous courses of treatment at other hospitals The standard course produced several feet of headless worm, then the parasite grew again The man, being rather desperate, was treated with a second course of rather heroic proportions After 4 days' fluid diet, with twice the standard doses of purgatives he was given eight doses of 30 minims of male fern at quarter hour intervals, and oil of chenopodium 1 ml and carbon tetrachloride 3 ml made up to 1 fl oz with liquid paraffin The complete worm was then passed Such a course would be dangerous to anyone in poor health, this patient, a healthy man aged 34 was quite ill for 24 hours after treatment However, "the man recovered from the dose, the worm it was that died"

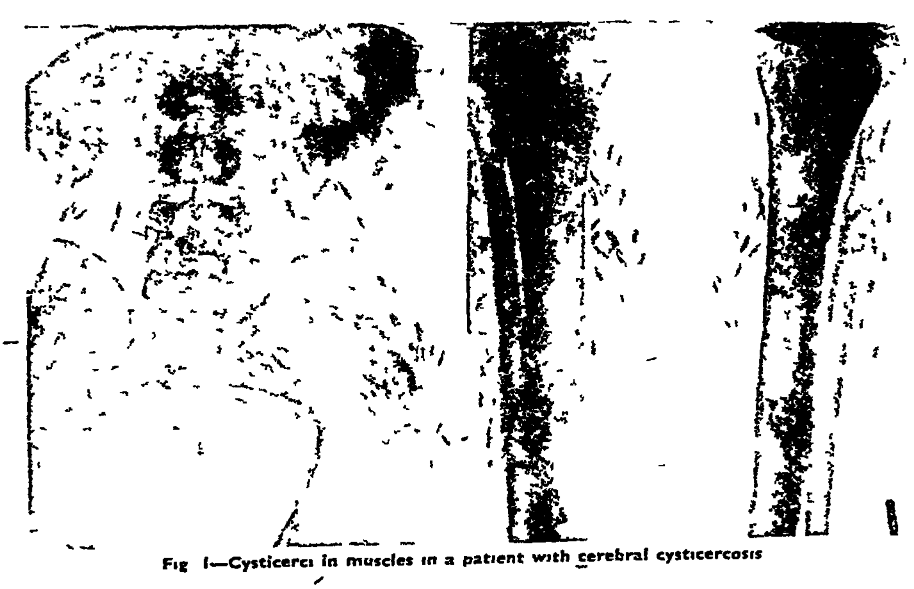


Fig 1—Cysticerci in muscles in a patient with cerebral cysticercosis

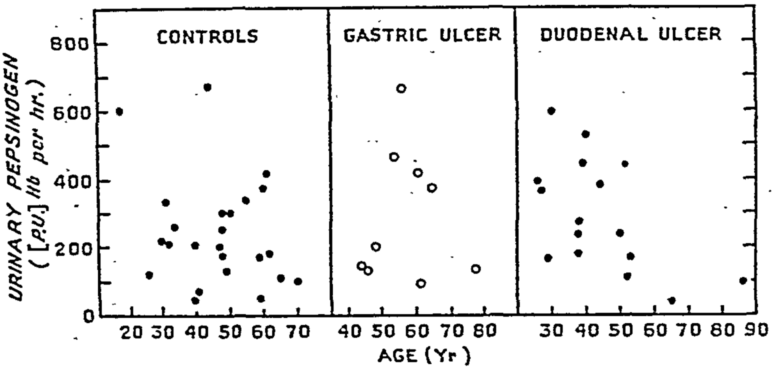

Fig. 1—Amount of pepsinogen excreted in urine of females according to age.

suggested by Northrop (1932) the symbol [P.U.]^{Hb} is used to mean peptic units in a standard hæmoglobin assay.

RESULTS

149 persons of either sex were studied: there were 60 controls free from dyspepsia, 61 patients with duodenal ulcer, and 28 patients with gastric ulcer.

Controls

These 60 persons, 36 males and 24 females, aged 15–88, comprised ambulant patients in hospital and hospital staff, chosen to correspond approximately to the duodenal-ulcer group in age. As will be seen from table I the age-distribution was similar between the sexes, and age appeared to have no consistent effect on the urinary excretion of pepsinogen. The average urinary excretion of pepsinogen in the 36 males was 195 [P.U.]^{Hb} per hour (S.D. ± 132), and in the 24 females 244 [P.U.]^{Hb} per hour (S.D. ± 154). This difference is not significant at the 5% level ($t = 0{\cdot}415$, $0{\cdot}05 < P < 0{\cdot}10$).

Peptic Ulcer

It soon became apparent that in patients with peptic ulcer certain differences existed within the group. These differences are related to sex of the patient, the site of the ulcer, and the length of history of dyspepsia.

Sex differences.—In the presence of an ulcer, irrespective of the site and length of history of dyspepsia, females excreted normal amounts of pepsinogen in the urine (fig. 1). In confirmation of previous results (Podore et al. 1948, Janowitz et al. 1950) it was found that in males there was a difference between the controls and patients with peptic ulcer, whether gastric or duodenal (fig. 2), though within these groups other factors seem to play a part (see below). Further observations deal with males only.

Site of ulcer.—The 19 male patients with gastric ulcer could be divided into two categories: (1) the 12 patients with the ulcer on the lesser curvature excreted normal amounts of pepsinogen (average 234 [P.U.]^{Hb} per hour); and (2) the 7 with the ulcer at or beyond the lesser curvature excreted an average of 597 [P.U.]^{Hb} per hour, thus resembling the 45 male patients with duodenal ulcer who excreted an average of 435 [P.U.]^{Hb} per hour (table II). Therefore, on this criterion of gastric function, gastric and duodenal ulcers may be grouped functionally into two groups: (1) those of the lesser curvature of the stomach in patients who excrete normal amounts of urinary pepsinogen; and (2) those at or beyond the lesser curvature—i.e., antroduodenal ulcers—in patients who excrete amounts significantly greater than normal.

TABLE II—AVERAGE URINARY EXCRETION OF PEPSINOGEN IN MALES

Group	No. of cases	Pepsinogen ([P.U.]^{Hb} per hr.)	S.D.
A, controls	36	194	± 132
Gastric ulcer:			
B, on lesser curvature ..	12	234	± 155
C, beyond lesser curvature ..	7	597	± 295
D, duodenal ulcer	45	435	± 379

By "t" test: difference between A and B $0{\cdot}05 < P < 0{\cdot}10$
" " A " C $P < 0{\cdot}001$
" " A " D $P < 0{\cdot}001$
" " B " C $P < 0{\cdot}01$
" " B " D $0{\cdot}02 < P < 0{\cdot}05$
" " C " D $0{\cdot}05 < P < 0{\cdot}10$

Length of history.—The length of history is taken as the continued presence of symptoms, complications, or radiological signs of an ulcer without complete intermission of longer than five years. In this group of 45 duodenal ulcers and 7 prepyloric ulcers it was clear that the urinary excretion of pepsinogen increased progressively with the length of history (tables III and IV).

To prove that this increase in urinary pepsinogen in patients with duodenal ulcer was solely related to the length of history of dyspepsia and not to age, which increases with the increasing length of history, a partial correlation was made between urinary pepsinogen (u), age (a), and history (h):

Correlation coefficient $r_{uh\cdot a} = 0{\cdot}639$ $P < {\cdot}001$
$r_{ua\cdot h} = -0{\cdot}0296$ $0{\cdot}5 < P$
$r_{ha\cdot u} = 0{\cdot}445$ $P < {\cdot}001$

This showed that there was a highly significant correlation between pepsinogen and history, and between age and history, at the 0·1% level, but no correlation at all between pepsinogen and age, leaving the third factor out of account in each instance. With less than a five-year history the urinary excretion of pepsinogen was within normal limits, but was increased with longer histories (table IV). The differences between duodenal ulcers with histories less than five years and duodenal ulcers with histories more than five years are highly significant statistically at the 0·1% level. A similar analysis for ulcers of the lesser curvature in males and for

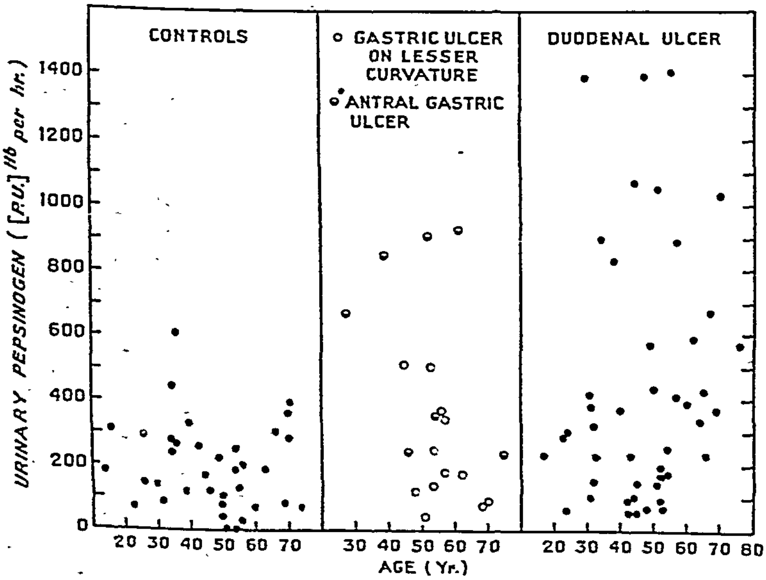

Fig. 2—Amount of pepsinogen excreted in urine of males with different kinds of peptic ulcer and of controls.

TABLE III—ANTRODUODENAL ULCERS IN MALES ARRANGED ACCORDING TO LENGTH OF HISTORY (NUMBER OF CASES)

Urinary excretion of pepsinogen ([P U]^{Hb} per hr)	Duodenal ulcers							Prepyloric ulcers	
	Dyspeptic history (yr)							Dyspeptic history (yr)	
	<2	2–4	5–9	10–14	15–19	20–24	25 or more	<5	> 5
1000–1500	—	—	—	2	1	1	2	—	—
750–999	—	—	2	—	—	1	—	—	3
500–749	—	—	—	—	1	2	1	—	1
400–499	—	1	—	1	2	—	—	—	—
300–399	3	1	1	—	1	1	—	—	1
200–299	2	1	1	1	—	1	—	2	—
100–199	3	5	—	—	—	—	—	—	—
0–99	5	1	—	—	—	—	1	—	—

gastric and duodenal ulcers in females did not reveal any relation between urinary excretion of pepsinogen and length of history, the excretion being similar to that in the controls

DIAGNOSTIC SIGNIFICANCE OF URINARY PEPSINOGEN

Apart from the physiological significance of disturbed urinary excretion of pepsinogen in patients with peptic ulcer, it was originally hoped that this test might prove to be of some value in the diagnosis of peptic ulcer Table v shows that this hope was not sustained by the findings that in all cases, except in male patients with antroduodenal ulcers with a history of more than five years' dyspepsia, the amount of pepsinogen excreted in the urine was no different from that excreted by the controls *The estimation of urinary pepsinogen therefore seems to have a very limited application in routine* gastroduodenal diagnosis

DISCUSSION

From the results of estimations of urinary pepsinogen in patients with gastric or with duodenal ulcer and in controls, points of difference emerge which have not been commented on by previous workers

In the controls age and sex seem to play no part in the regulation of pepsinogen excretion In patients with peptic ulcer, however, several *factors seem to* affect the urinary excretion of pepsinogen—namely, the sex of the patient, the site of the ulcer, and the length of history of dyspepsia

Podore et al (1948) studied males only and did not differentiate gastric from duodenal ulcers Janowitz et al (1950) did not comment on any sex difference and, while separating *gastric from duodenal ulcers, reported* only 4 gastric ulcers; they also included stomal a jejunal ulcers with duodenal ulcers Results in 6 patie with stomal ulcers in the present study (but not i above) showed normal urinary excretion of p Neither Podore et al (1948) nor Janowitz et al (195 reported any correlation with the length of histor of dyspepsia Varró et al (1952) reported normal urinar excretion of pepsinogen in their few cases of duodenal ulcer

TABLE IV—ANALYSIS OF RESULTS IN ANTRODUODENAL ULCERS ACCORDING TO LENGTH OF HISTORY (MALES)

Length of history (yr)	No of cases	Mean length of history (yr)	Mean age (yr)	Mean urinary excretion of pepsinogen ([P U]^{Hb} per hr)	—
Duodenal ulcer					
0–4	22	1 34	13 2	186	*a*
5–9	4	6 7	34 0	594	*b*
10–19	9	13 9	47 7	694	*c*
20 or more	10	25 5	59 2	688	*d*
Total	45	10 52	46 6	435	*e*
Prepyloric gastric ulcer					
0–4	2	0 15	60 5	237	*f*
5 or more	5	7 8	46 2	741	*g*
Total	7	5 6	50 0	597	*h*

By t test difference between *a* and *b* $P<0\ 001$
,, ,, *a* ,, *c* $P<0\ 001$
,, ,, *a* ,, *d* $P<0{\cdot}001$
,, ,, *h* ,, *e* $0\ 02<P<0\ 10$
,, ,, *f* ,, *g* $0\ 2<P<0\ 5$

It is abundantly clear that sex differences are considerable, *in that females all excrete normal amounts* of pepsinogen, irrespective of the presence of an ulcer (fig 1) or of the length of history of dyspepsia

In males ulcers may be divided functionally into those on and those beyond the lesser curvature of the stomach. Males with the ulcer on the lesser curvature excrete normal amounts of pepsinogen in their urine, whereas those with the ulcer beyond the lesser curvature—either prepyloric gastric or duodenal ulcer—excrete significantly increased amounts of pepsinogen

In males with an antroduodenal ulcer the amount *of urinary pepsinogen is normal initially* with a history of dyspepsia less than five years and increases progressively with the increased length of history, even as the gastric acidity in duodenal ulcers increases with the length of history (B I Hirschowitz and T D Kellock, unpublished data)

TABLE V—CASES SUBDIVIDED BY SEX, SITE, AND LENGTH OF HISTORY AND ARRANGED ACCORDING TO AMOUNT OF URINARY PEPSINOGEN

Urinary excretion of pepsinogen ([P U]^{Hb} per hr)	No of males				No of females		
	Con trols	With gastric ulcer on lesser curva ture	Antroduo denal ulcer		Con-trols	Gastric ulcer	Duo denal ulcer
			<5yr	> 5yr.			
0–99	10	3	6	1	4	1	2
100–199	11	4	8	—	7	4	4
200–299	8	1	5	3	5	—	3
300–399	5	2	4	4	5	1	3
400–499	1	—	1	3	1	2	2
500–749	1	2	—	5	2	1	2
750–999	—	—	—	6	—	—	—
1000–1500	—	—	—	6	—	—	—
Total	36	12	24	28	24	9	16

The increase in gastric activity shown both by the urinary excretion of pepsinogen and by the gastric acidity in the long-continued presence of an antroduodenal ulcer in men suggests that gastric hypersecretion may be an effect rather than a cause of the ulcer, or that both may be the result of a common stimulus This concept is not new (cf Shay et al 1942), but it has received little general support

In view of the reports of Podore et al (1948) and of Janowitz et al *(1950) I hoped that this test* might prove to be of some diagnostic value However, the finding of normal values in females, in males with a gastric ulcer in the lesser curvature, and in many males with an antroduodenal ulcer, makes it valueless in *the routine* diagnosis of peptic ulcers—*a conclusion reached* by Benderskey (1890)

SUMMARY

Pepsinogen, arising from the gastric mucosa, is excreted in the urine Its measurement is used for indirect assessment of part of the secretory activity of the stomach

The urinary excretion of pepsinogen was measured in 149 patients—60 controls, 61 patients with duodenal ulcer, and 28 with gastric ulcer

Females, with or without an ulcer, all excreted normal amounts of pepsinogen in the urine

All male patients with a gastric ulcer on the lesser curvature excreted normal amounts of pepsinogen in

OLD WIVES' TALES

It is interesting that many patients have a lore of their own concerning the clinical features and treatment of tapeworm.

One woman had been told by her grandmother how to treat the worm. "First," she said, "you must starve yourself till the worm is very hungry, then you open your mouth, hold a piece of bacon in front of you, take a pair of scissors in one hand and wait. Then the worm will make a leap for the bacon and you can cut off its head." I confess with regret that the thirteen cases reported here were treated by the orthodox ritual of purgation and male fern, rather than the more sporting methods advocated by the grandmother.

Other superstitions are that if the host drinks enough gin this makes the worm "turn its head the other way and come away natural." Also it is believed by some that the increased hunger occurring in certain cases of tapeworm infection is due to the voracious appetite of the worm and that if the host does not eat enough to satisfy his unwelcome guest the worm in its desperate search for food "may come up in your throat and choke you," or worse still "it may eat away your inside." Stranger still is the widely circulated story that many of the pills sold to reduce weight are in reality tapeworm eggs and that to ensure they are safe the pills should be left overnight in a little water, when, if they are eggs, they will have hatched into a worm by the morning.

SUMMARY

Thirteen cases of infestation by beef tapeworm are described.

Six of the patients complained of symptoms, consisting of sudden abdominal cramps, giddiness, and hunger, which in three cases were severe. The majority of them had eaten raw meat.

Infestation by tapeworm should be included in the differential diagnosis of obscure abdominal pain.

There is no evidence that infestation by tapeworm is becoming less common in this country.

A standard course of treatment with filix has cured twelve of the patients. The remaining patient responded to a second and stronger course with added carbon tetrachloride and oil of chenopodium.

DUNN NUTRITIONAL LABORATORY, UNIVERSITY OF CAMBRIDGE, AND MEDICAL RESEARCH COUNCIL

THE investigations recorded here began in 1950 in an attempt to throw new light on the puzzling problem of the apparent interrelation between adrenal function and vitamin-C metabolism.

Presumptive evidence for the existence of this interrelation is afforded by such facts as the following: (1) the silver-staining properties of the adrenal cortex (Szent-Györgyi 1928) attributable to vitamin C, which is present in remarkably high concentrations both in the cortex and in the medulla (Harris and Ray 1932, 1933); and (2) the action of adrenocorticotropic hormone (A.C.T.H.) in bringing about a transient fall in the concentration of the vitamin within the adrenal (Sayers et al. 1944).

Our original object in these experiments was to ascertain whether the repeated administration of large doses of A.C.T.H. to guineapigs would lead to so great a loss of vitamin C from their adrenals as to increase the effective requirement for the vitamin, and thereby to hasten the onset of scurvy in guineapigs kept on diets deficient in it. Although the answer to this question was substantially negative, some unexpected observations were made—particularly the fact that, in the guineapigs given these repeated injections of A.C.T.H. there resulted a remarkable and continuous increase in the weight of the liver. As we have published hitherto only brief summaries of our conclusions (Bland et al. 1952, Hughes et al. 1952, Harris 1953), it seems desirable to give some typical numerical examples of our actual data; and we are also taking the opportunity, at the same time, to present some of our later results.

EXPERIMENTAL

Unless otherwise stated, the findings given below relate to experiments in which young guineapigs weighing 300–350 g. had a course of intramuscular injections of A.C.T.H. (2 mg. of Armour standard L.A.1.A., four times daily). The standard "basal diet" consisted of Sussex ground oats 650 parts, bran 144, dried egg-yolk 80, dried brewers' yeast 108, and salt mixture 18, supplemented with 25 mg. of ascorbic acid daily (omitted for experiments with scurvy), 4 drops of halibut-liver oil weekly, and water ad lib. In other tests a "natural" diet was used instead, consisting of Sussex ground oats 1000 parts, and bran 220, supplemented with 15 g. of cabbage per animal per day, water and hay ad lib., and roots when available. None of our guineapigs was subjected to hypophysectomy. Rats, when used, were kept on the standard "synthetic" diet used in this laboratory, and rabbits on the above-mentioned "natural" diet, with cabbage ad lib.

RESULTS

(1) *Effect of A.C.T.H. on Vitamin-C Metabolism*

Contrary to our expectations, it was found that the vitamin-C economy of the body as a whole was not appreciably changed. Although the concentrations of ascorbic acid in the liver and adrenals of the guineapigs were diminished, the total quantities of ascorbic acid in these two organs (both of which were enlarged as a consequence of the treatment) were not substantially affected (fig. 1). The administration of A.C.T.H. did not hasten the onset of scurvy in guineapigs on the deficient diet; nor did it increase the rate of depletion of ascorbic acid from the liver or the adrenals during the development of deficiency.

(2) *Effect of A.C.T.H. on A.A.: D.H.A.A. Equilibrium in the Adrenals*

After a single injection of A.C.T.H. no substantial change was found in the relative proportion of dehydroascorbic acid to ascorbic acid present in the adrenals of guineapigs, although the concentration of ascorbic acid was temporarily depressed.

(3) *Liver Weights*

In the young guineapigs given the standard course of injections of A.C.T.H. (see above) a remarkable increase was seen in the weight of the liver, which was already apparent after only two days and continued thereafter day by day—e.g., up to ten days—when the increase had reached a value of about 50%, compared with the controls (fig. 2). This increase in weight has now been observed repeatedly in nine series of tests extending for over twenty months and involving over 350 animals, and is statistically highly significant ($P = < 0{\cdot}01$).

Antibiotics in Action

REVIEWING problems affecting the search for micro-organisms that produce antibiotics, ROUTIEN and FINLAY[1] forecast that unsolved problems will continue to attract research-workers to this subject. A satisfactory agent against the smaller viruses has not yet been discovered; possibly an antibiotic might be useful in the treatment of cancer; and better agents against mycobacteria and protozoa are much needed. The resources of industrial firms are well organised and skilfully directed in the search, which seems for the present to be largely concentrated on the rewarding genus streptomyces. Many programmes of systematic exploration are being undertaken, chiefly on a great variety of soils from all parts of the world but also on such varied material as growing plants, culture collections, waters, muds, bogs, composts, decaying leaves, earthworms from graveyards, sewage, fermentations, and anthills. Studies have been made, too, of bacteria from human infections undergoing resolution,[2] and there have been attempts to induce antibiotic-producing mutants among micro-organisms by X-ray and ultraviolet irradiation.[3] The search for new antibiotics is largely empirical, and individual workers with few resources should not be discouraged, for an acute observer whose mind is prepared and whose approach is flexible may still hope to meet and recognise one of the lucky chances which have so often led to great discoveries.

Empirical methods, however, are not enough. The important developments of chemotherapy have naturally been followed by explanations of the properties of antibiotics in terms of their chemical reactions with living matter. Speculation and research on this topic began with EHRLICH's side-chain theory, and new reports continue to appear at short intervals. Since we last commented on this subject[4] much of the recent knowledge has been reviewed in a symposium arranged by the Society of American Bacteriologists.[5] Clearly, many different biological properties of bacteria are affected by some of the antibiotics, and it is extremely difficult to devise critical experiments to show which of the interactions between bacterium and drug is of real importance and whether the resultant modifications of bacterial metabolism affect the organism directly or indirectly. SMITH[6] named forty-nine bacterial metabolic processes and enzyme systems which have been studied for their sensitivity to chloramphenicol, but he considered that only two of these were clearly significant as causes of growth inhibition—namely, interference with utilisation of amino acids and with the metabolism of fats and esters. He cited work by GALE and PAINE[7] which suggests that chloramphenicol may possibly act by inhibiting protein synthesis because of its action in preventing the formation of combined glutamate and the utilisation of ammonia. An important point about chloramphenicol inhibition of esterase activity is that this action is found with esterases isolated from tissue cells as well as with bacterial esterases, but that intact tissue cells—of horse-liver for example—possess a mechanism which prevents the antibiotic from inhibiting the esterase activity of the host cells. HOBBY,[8] reviewing work on aureomycin and terramycin, mentioned evidence for their action on the phosphorylation system on the metabolism of tricarboxylic acids and α-ketoglutarate, and on the oxidation of glycine, glutamic acid, and aspartic acid. She referred to AJL's[9] view that the actions of terramycin and aureomycin are similar, and that the site of their action may involve the initial step in acetic-acid oxidation. The hypothesis that antibiotics stimulate animal growth simply by inhibiting intestinal organisms is now in some doubt, because growth responses have been observed with doses of antibiotics which are too small to act on the intestinal flora; it appears that the drugs may act by increasing absorption of nutrients as well as by inhibiting drug-sensitive pathogens.

OGINSKY[10] discussing the mode of action of streptomycin drew attention to its inhibition of aspartate and amino-acid oxidation by *Bacterium coli* and to other respiratory effects causing increased acetate formation. In bacterial cells capable of oxidising acetate, no streptomycin inhibition of the oxidation of pyruvate and oxalacetate could be demonstrated, but the oxidation of these substrates was much inhibited if acetate oxidation was slight or absent. Studies of the action of streptomycin on the tubercle bacillus indicated that the oxidation of the long-chain fatty acids is sensitive to the drug, but that oxidation of the short-chain fatty acids is not, suggesting that their metabolism by the organism may also be different.

PRATT[11] drew attention to changes in the morphology and staining reactions of penicillin-treated organisms. These changes are the same as those described by STEARN and STEARN[12] as characteristic of "starving" bacteria, which fits in with the knowledge that penicillin prevents staphylococci from absorbing glutamic acid and various inorganic substances and generally interferes with the ability of

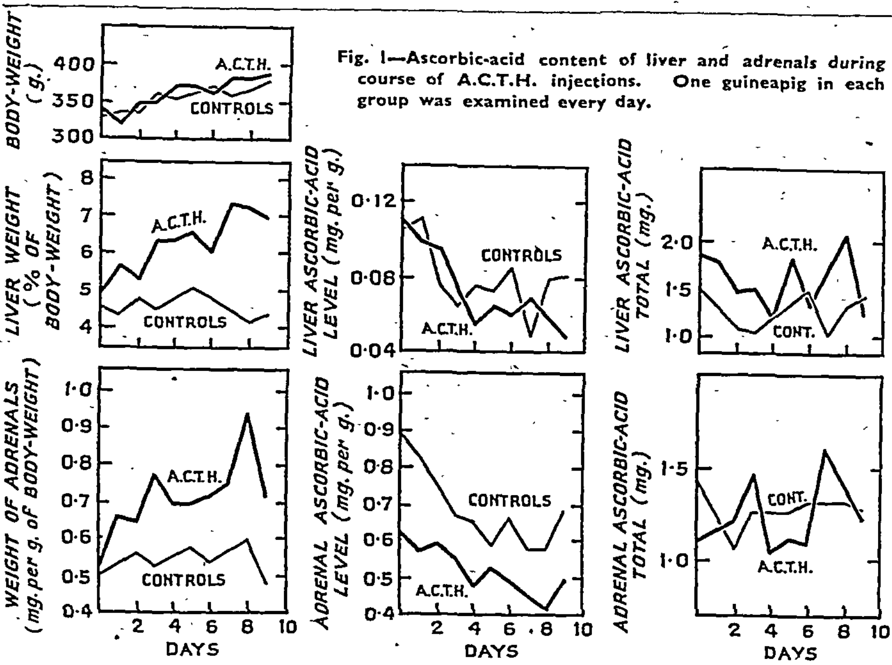

Fig. 1—Ascorbic-acid content of liver and adrenals during course of A.C.T.H. injections. One guineapig in each group was examined every day.

In adult guineapigs A.C.T.H. had a similar effect to that in young growing ones in causing a great increase in the liver weight (av. = 39%, after 10 days, statistically highly significant).

(4) *Liver Weights : Dose-response Curves*

Dose-response curves have been constructed, relating the increases in liver weight observed to the size of the dose of A.C.T.H. administered (fig. 3). It seems likely that our findings may have possible uses in biological assay, as in characterising the action of different hormones —e.g., the various A.C.T.H. fractions (see also below under *Cortisone*).

(5) *Composition and Structure of Enlarged Liver*

Analyses were made of the fat, protein ("Kjeldahl-nitrogen"), carbohydrate, and water contents of the enlarged liver, and the composition of the "increment" was calculated by difference (fig. 4). It will be seen that during the first day or so the increased weight of the liver was due essentially to extra glycogen and water but thereafter there was also an appreciable addition of protein. Histological examination by Dr. C. P. Cherry, at the Strangeways Research Laboratory, showed that there was an increase in the size of the liver cells, which was attributable to an increased volume of the cytoplasm and was equivalent in magnitude to the increase observed in the weight of the whole liver.

Under the conditions of our experiments the A.C.T.H. caused a diminution in the percentage of fat in the liver and not a rise (as might perhaps have been expected from previous reports relating to other species). There was little effect on the concentration of sulphydryl compounds (including glutathione) in the liver.

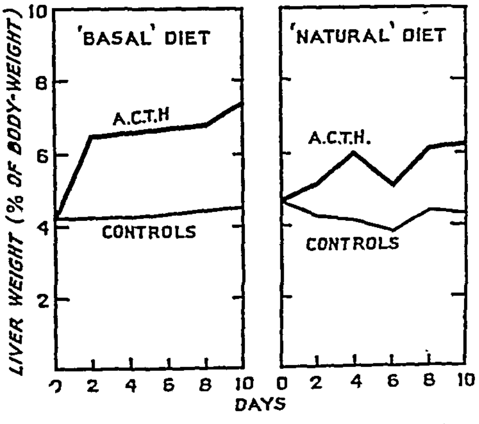

Fig. 2—Weight of liver (average of group) during a course of A.C.T.H. injections.

(6) *Long-term Injections*

When the injections of A.C.T.H. were continued for longer periods, up to forty days, the general effect on the chemical composition of the liver was similar—i.e., a further increase in the amounts of water, protein, and glycogen (absolute weights) in the liver, compared with the controls (or, in terms of percentages, an increase in glycogen, but some decrease in the protein and fat, and little change in the water).

(7) *Result of Discontinuing the Treatment.*

When, after ten days, the injections of A.C.T.H. were discontinued, there followed a sharp fall in the weight of the liver, with the result that two days thereafter it weighed no more than the control (and, from three to thirty days subsequently, was about 10% smaller). The glycogen in the liver decreased to within the normal limits, of the controls, within about a couple of days, and the protein some days later.

(8) *Effect of Cortisone on Liver Weight and Composition*

In young guineapigs cortisone had an effect similar to that of A.C.T.H. in increasing the weight of the liver, but to an even greater degree. For example, after ten days' treatment with intramuscular cortisone acetate 7·5 mg. per day in two doses, there was an average increase in weight of 50% ; and with 15 mg. per day (see fig. 5) an average increase of 72% after four days, or of 123% after ten days ($P = \leqslant 0{\cdot}01$).

The effect of cortisone on the proximate chemical composition was similar to that observed with A.C.T.H. (fig. 4).

Incidentally, the injections of cortisone and A.C.T.H. had the effects, as expected, of diminishing and of enlarging, respectively, the weights of the adrenals (cf. figs. 1 and 5).

(9) *Effect of Cortisone on Weights of Other Organs*

In the young guineapigs given the repeated injections of cortisone there was no significant change in the average weights of the pancreas, lungs, heart, thymus, or spleen. There was, however, an increase in the average weight of the kidneys, amounting to 8% after 7·5 mg. of cortisone per day for 10 days, or of 20% after 15 mg. per day, these figures being statistically "significant" ($P = 0{\cdot}05$) and "highly significant" ($P = \leqslant 0{\cdot}01$) respectively. A possible effect on the weights of the testes seemed less consistent, and needs further study (33% increase in weight after 7·5 mg. of cortisone acetate per day, with $P = 0{\cdot}05$—i.e., "significant"—but no significant effect after 15 mg. of cortisone acetate per day).

(10) *Species Differences*

In young rats, contrasted with guineapigs, A.C.T.H. had no important effect on liver weight, and cortisone caused some loss in the weight (absolute) of the liver, in place of a rise. (At the higher levels of dosage of cortisone, with the consequent decline in body-weight, the liver of the rats lost somewhat less weight than did the body as a whole, and there was thus some increase in the relative weight of the liver, although not in its absolute weight.)

Again, in chicks and mice given A.C.T.H. no important changes were observed in liver weight.

organisms to retain such substances as lipoids, fatty-acid hydrolysates, and nucleotides It appears that penicillin, ribonuclease, and cobra venom exert many similar actions on bacteria , and this supports the idea that penicillin may interfere with the phosphorylation of important nucleotides and that its effect on bacteria may depend on excessive dehydrogenation of reduced substances—probably those bearing sulphydryl groups If these assumptions are correct, penicillin will be most effective at a concentration which accelerates the transfer of hydrogen from —SH or other reduced groups without seriously hindering the activity of hydrogen acceptors On this basis it would be expected that the most efficient and rapid antibacterial effects would follow the use of the least concentration capable of producing irreversible injury to the bacteria At an appropriate lower concentration than the optimum, penicillin might be expected to act as a growth stimulant, and at concentrations much higher than the optimum the drug might so impair the activity of hydrogen acceptors as to give some protection to the hydrogen donors against the rapid, irreversible dehydrogenation on which its action may depend There is clinical and experimental evidence for the view that bacteria are less efficiently killed by concentrations of penicillin and other antibiotics above and below the optimum[13]

Isoniazid has not yet been so intensively studied as the other antibiotics, but an explanation of its mode of action might be particularly interesting since it is active only against mycobacteria **Barclay** et al ,[14] using isoniazid labelled with C^{14}, studied the uptake of drug and its effect on bacterial growth in a normal culture and in a culture of a drug-resistant variant of the same strain of *Mycobacterium tuberculosis* (H37RV) Isoniazid did not halt growth immediately , the tubercle bacilli continued to multiply, at first quite rapidly, but then more and more slowly until growth ceased at a point when the bacterial population had approximately doubled The isoniazid effect was not influenced by bacterial numbers or phase of growth, or by changes in concentration of drug within the range 0 05–100 µg per ml The organisms whose growth was arrested retained some enzyme activity and were neither killed nor lysed Those subjected to low concentrations of drug resumed growth in about two weeks and were then resistant to the concentration of drug in the medium All this contrasted strikingly with the effects of streptomycin, which arrested growth almost at once, stopped enzyme activity, killed the organisms, and led to perceptible lysis of the culture in three days Resistant organisms eventually appeared, however, and growth was resumed The radioactive isoniazid clearly showed that the sensitive strain of bacteria took up the drug, whereas the resistant strain did not Isoniazid action thus has points in common with sulphonamide action, which may suggest that absorption of the drug interferes with the formation of an essential metabolite

Reviewing problems of combined chemotherapy, **Garrod**[15] has declared that we still do not know enough about the mode of action of antibiotics to explain with certainty why the use of two drugs helps to prevent the development of resistant bacteria Probably the second drug blocks the metabolic pathway developed by a resistant organism to circumvent the effect of the first drug Since so many combinations of drugs are effective in this way, **Garrod** suggests that by studying their effects it may be possible to discover more about the points of attack of individual drugs Clearly, a great deal of laboratory work lies ahead Some of this, as **Garrod** points out will be extremely laborious—work on a case of enterococcal endocarditis which he studied occupied well over 100 hours of laboratory time—and much of the work, as **Wyss**[16] has said, resembles groping in the dark Nevertheless the recent contributions show that we have a considerable body of new knowledge about the biochemistry and physiology of micro-organisms

Children in Road Accidents

Our predecessors fenced off those dangerous trains, and forbade the public to invade the permanent way Motor-cars do not run at fixed times, do not announce their approach as noisily as trains, and are just as dangerous to life and limb , yet we all share the same roads—young and old, halt and spry, motorists, cyclists, and pedestrians alike—and we look like doing so for the rest of this century Road accident figures are so monotonously high that those who wish to sting us into some sense of responsibility have to use devices to touch the imagination—telling us, for example, that on our roads during 1951 at least one child was killed or injured in every fifteen minutes This fact alone should make us *demand to know the ages of the children*, and what they were doing at the time , and an important study[17] along these lines has just been published by the Economic Research Council for the Children's Safety Crusade Trust, founded by the late Mr **Gordon Stewart** The trust have presented their report to the National Federation of Women's Institutes, who gave them substantial help in deciding on age span groupings of children, and offered many opinions which the subsequent analysis of figures proved to be shrewd and sound

With Prof **Harry Jones** as chairman, the study group[18] have discussed their findings in terms of " risk-rates " These are calculated to represent the risk of injury per 10 million children per day within each age-group, and are therefore strictly comparable thus, if the risk-rate of a 12-year old boy on a June schoolday is 20, and that of a 4-year old on a similar day is 150, the risk to the younger boy is $7^1/_2$ times greater than the risk to the elder The study group have taken it that a risk-rate of 20 (the average risk of a child as *passenger* on the road) is probably as

With rabbits, on the other hand, the effect of A.C.T.H. on the liver was similar to that in guineapigs, the increase in weight being very pronounced (48% increase, after ten days, on 24 mg. of A.C.T.H. daily, in 3 doses per day), and statistically "highly significant" (P =0·01).

COMMENTS

A.C.T.H. and Vitamin-C Metabolism

Our findings on A.C.T.H. in relation to vitamin-C requirements have been essentially negative. Previous published reports have been somewhat conflicting, some observers—e.g., Hyman et al. (1950), Eisenstein and Shank (1951), and Long (1947)—reporting that A.C.T.H. may apparently "spare" vitamin C, and others—e.g., Clayton and Prunty (1951)—noting an absence of any such effect.

There have been indications also (Stewart et al. 1953, Cornforth and Long 1952, Loxton and Le Vay 1953) that both A.C.T.H. and cortisone may affect the equilibrium between ascorbic acid and dehydroascorbic acid in the blood. Under the conditions of our own tests we found no change in A.A. : D.H.A.A. ratio, so far as the adrenals were concerned, following on the injections of A.C.T.H.

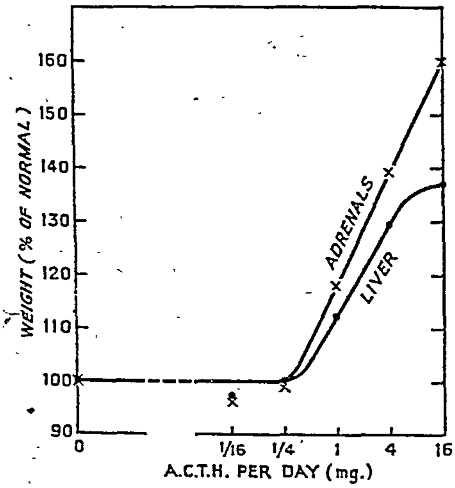

Fig. 3—Dose-response curve, showing increase in weights of liver and adrenals (after 10 days) depending on amount of A.C.T.H. administered daily (log. scale).

Liver Enlargement

It is remarkable that the massive increase in liver weight in guineapigs after A.C.T.H. does not seem to have been noted by previous investigators. The explanation perhaps is that the guineapig has not been the animal most usually employed in research on A.C.T.H. Also, other unusual features in our experiments were the prolonged course of injections and the absence of hypophysectomy.

It seems clear from our results that this action of A.C.T.H. on the liver is to be attributed largely if not entirely to its influence in stimulating the production of cortisone. In terms of proximate components, the enlargement is associated with an increase in the absolute amounts of glycogen, water, and protein—i.e., Kjeldahl-nitrogen. The effect of cortisone in stimulating glycogen production is, of course, already well known. The more novel feature in our results is what we may term the "intracellular œdema." The fact that there is some increase in the protein in the liver, but that it is not in full proportion to the total increase in weight of the liver, can perhaps be most easily interpreted as representing the result of an increased passage of lymph into the liver. We cannot, however, rule out the possibility that some gradual building up of extra protein may take place as the functional response of the liver to the increased activity put upon it, under the stimulus of the cortisone. More detailed analyses of the various nitrogenous fractions, in place of the simple Kjeldahl-nitrogen determinations here recorded, are obviously needed to throw further light on such questions.

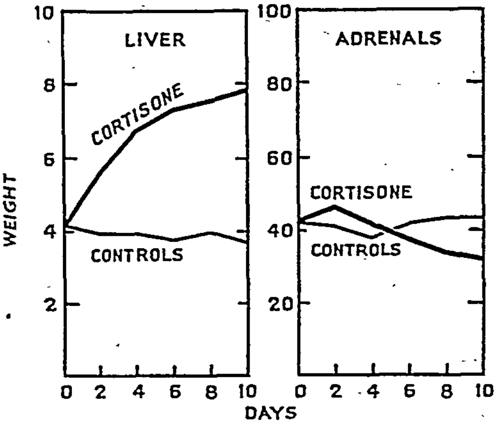

Fig. 5—Weights of liver and adrenals (average of group) during a course of cortisone injections. (Liver weights in g. per 100g. body-weight; adrenal weights in mg. per 100g. body-weight.)

Species Differences

The cause of the species difference in the liver enlargement is uncertain. Guineapigs, together with primates, are unique, it is true, in being the only species known to need vitamin C in their diet, other species being able to synthesise it. However, the general negative trend

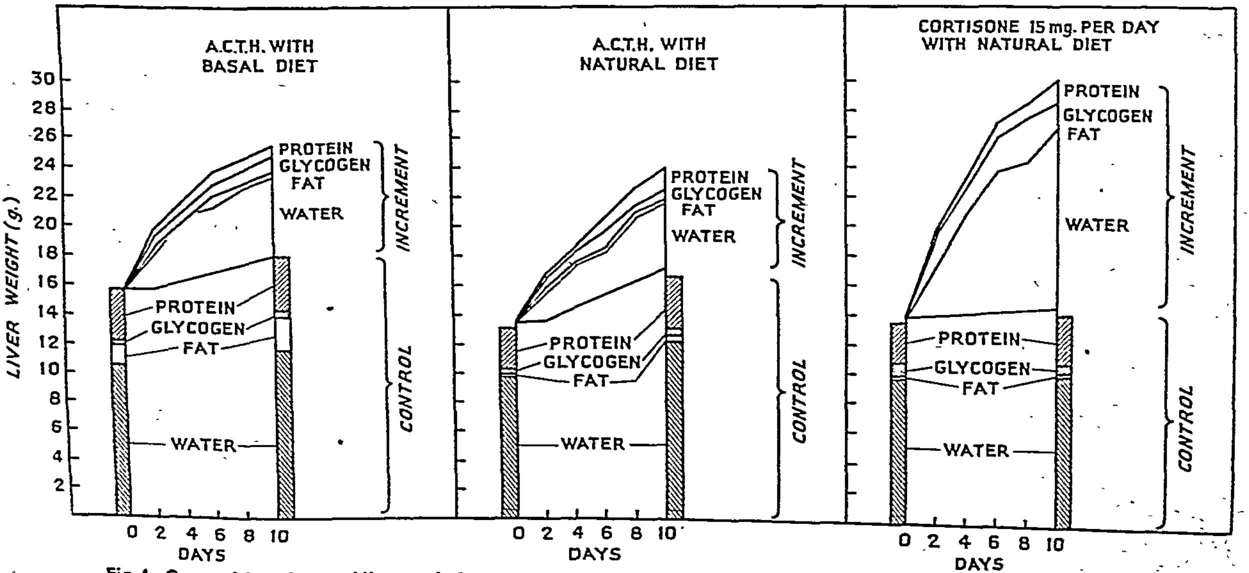

Fig. 4—Composition of normal liver, and of newly formed "increment," resulting from action of A.C.T.H. or of cortisone.

low as it is possible to get it and they grade risk-rates of 20–80 as "serious" of 80–140 as "tragic," and over 140 as "catastrophic."

It should perhaps be noted that children as "passengers" are classed as those boarding, alighting or falling from a vehicle, sitting or standing inside a vehicle, or stealing a ride, and it is odd to notice that though none of these occupations carries a great risk for children easily the highest figures—ranging up to 31—fall in the columns for those sitting or standing inside a vehicle, where no blame can possibly attach to them.

The study group have analysed the 1951 figures for child casualties so as to show risk-rates at different ages at different times of the year, at different times of day, in school term-time and during the holidays, for boys and girls, for child pedestrians, passengers and cyclists and according to what the child was doing at the time. One finding is new and outstanding. It has long been recognised that the risk-rate for young children just starting school and perhaps using the roads unattended for the first time, is very high indeed—well into the tragic class for both sexes, and for boys often (indeed usually) in the catastrophic class. Thus the risk-rate for boys aged 5–7 during term time in 1951 ranged from 150 to 220. It has not been generally realised that the rates for boys of 15–16 the safest *pedestrians* in the country, are far in excess of these—even at some seasons of the year, twice or thrice as great. And the cause of these towering risk-rates is the bicycle.

The ironically named safety-bicycle is now so much a part of our civilisation that we have not perhaps observed that for modern road conditions it is growing dangerously out of date. Two-thirds of the child cyclists injured or killed in 1951 were doing nothing calculated to bring them to harm: they were riding straight ahead, neither overtaking nor turning. As this report says:

> "The child cyclist precariously balanced and unprotected is allowed to go on our heavily trafficked roads untrained, inexperienced, with his back to following faster, heavier vehicles, with no means of seeing what is overtaking him or of signalling unless he turns his head and takes one hand off the handlebars. Of course he swerves. And of course he pays the heaviest toll of the road."

As the study group point out on the next page at some age or other, and in some way or other, most of us nowadays—or anyhow most men—have to become efficient and responsible drivers on the road. But it is astonishing to find the group advocating the bicycle as the perfect tool for the prentice road user. 'Could we in fact devise any more suitable instrument for the beginning of their training than the bicycle?' they ask. The answer is surely "yes." Could we indeed have devised a worse one? Their own earlier paragraph makes it hard to believe that we could.

The truth is that the writers of this report, like the rest of us, are ambivalent about the bicycle: we have all gone through the stage, which they describe, in which it was a symbol of freedom and growing up—an exciting means of locomotion, our first real piece of machinery, stage one in the process of graduation to control of a mechanical vehicle on the roads. What asses we thought those careful seniors, urging caution. But the roads are very different now: every decade (war-times apart) makes a great and dangerous difference in the roads. It is true that the boy who learns to manage a bicycle safely in modern traffic has acquired road sense, but it is surely an extraordinary principle to allow the beginner to ride the most dangerous vehicle on the roads the moment he has learnt to keep a wobbling balance on it. The N.F.W.I. suggest that no child should be allowed to ride a bicycle on the road unless he has passed a test as to his own fitness and the fitness of his machine, and the study group supplement this with the sound proposal that a driving-mirror should be made part of his necessary equipment, as well as a simple direction indicator which he could operate without taking a hand off the handlebars.

In his introduction to the report Professor JONES urges that an efficient road system would do much to protect not only child cyclists but all road users: for though in nine out of ten accidents human error is the immediate cause, the true cause, he says, lies in "a combination of circumstances that create the situation in which the critical error is made." Such circumstances may be the poor lighting of a road, a hidden turning, a bad road surface, and the like. Again, *ignorance can contribute to accidents*: pedestrians walking in the roads without sidewalks often do not know that they should face the oncoming traffic, and van-drivers are seldom made aware of the risk of backing on to children playing behind them. Children are nowadays carefully taught kerb-drill in school, and at many school crossings patrols have been established to see them over at the appropriate times. But the parent or teacher finds it difficult to train children to keep on the pavement when for want of playgrounds they normally play in the street, and therefore hardly notice whether they are on or off the pavement: in 1951 nearly half the accidents to children aged 5–10 were the result of the child stepping, walking, or running off the pavement, and most of the rest happened to children crossing the road. Nevertheless, much could still be gained by better instruction of the public in the avoidance of accidents—not, as the group point out, in the flabby "do be careful" sense, but in specific risks at particular ages, as well as in the pedestrian's rule:

Keep to the left on the footpath,
Keep to the right on the road.

The writers make many ingenious suggestions for using existing channels of communication: the mother seeking maternity benefit should find road-safety advice on the forms of application; the infant-welfare centre could hang up posters; the family-allowance forms could carry information related to the exact ages of the children in a family; renewers of driving licences should be confronted with useful warnings about the types of vehicle they use; petrol stations might display items from the Highway Code; transport cafes would certainly use posters if asked; insurance companies might be induced to take a leading part in road-safety education (as they do in America); and buses might advertise the fact that 88% of accidents to people getting off London buses happen at places other than official stops. To these suggestions we should like to add another—that this mechanically minded age should develop a form of transport as cheap, handy, swift, and convenient as the bicycle, but without its murderous instability.

of our results on vitamin C, together with the additional fact that rabbits (not known to need vitamin C) behave like guineapigs argue against any explanation based on the difference of species in their vitamin-C metabolism. Nor can a species difference in regard to the release of cortisone after A.C.T.H. be held responsible, for in rats both A.C.T.H. and cortisone were equally ineffective in producing any liver enlargement. The possibility remains that guineapigs and rabbits are more liable than are other species to develop œdematous changes after A.C.T.H. (the addition of water being, as we have seen, an essential feature of the liver enlargement in our experiments); but, if that is so, it does not seem to have been hitherto reported.

In any event this spectacular effect on the liver seems of sufficient interest to warrant further study, in view of both the many side-effects produced by these hormones and the importance of the liver as the seat of so many diverse chemical activities.

MYSOLINE IN THE TREATMENT OF EPILEPSY

A. J. M. BUTTER

M.D. Edin.

MEDICAL OFFICER, ST. DAVID'S HOSPITAL, EDMONTON

FOR fifteen months 'Mysoline' (5-phenyl-5-ethyl-hexahydropyrimidine-4 : 6-dione) has been used in the treatment of epilepsy at St. David's Hospital, following favourable results obtained by Handley and Stewart (1952) at the David Lewis Epileptic Colony.

The patients selected for treatment were 58 sane male epileptics whose ages ranged from 20 to 66 and whose fits were not satisfactorily controlled by phenobarbitone, soluble phenytoin, 'Mesantoin,' phenyl-methyl-malonyl-urea, bromides, belladonna, amphetamine sulphate, or combinations of these.

The transition to treatment with mysoline was effected gradually, the existing medication being continued for the first two days, and then reduced step by step as the dose of mysoline was increased over a period of about a fortnight. Table I shows the dosage given in 0·25 g. tablets.

TABLE I—DOSAGE OF MYSOLINE USED

No. of patients	Daily dose of mysoline (g.) in divided doses
3	1·0
7	1·25
13	1·5
3	1·75
3	2·0

Almost all the patients complained of slight drowsiness or listlessness during the first day or two, especially before breakfast. 1 man complained of nausea. 2 became slightly ataxic, and 1 had slurred speech. 8 patients continued to feel drowsy, and in these cases, after a trial on reduced doses for periods varying from a fortnight to three months, the treatment was discontinued.

No other toxic symptoms or signs have been observed, and in most cases no complaints were made after the first few days. Urine and blood have at no time shown any abnormality.

In 29 cases treatment with mysoline was discontinued because of failure to reduce the number of fits and/or complaints of drowsiness.

During the period under review 2 patients died, neither fatality being in any way attributable to the medication.

Table II shows the results obtained.

As will be seen, 50% of the patients have benefited from the treatment, 35% of them because of a reduction in the number of their fits, and 15% because, although their fits were not reduced, they have felt better than when taking other drugs, such as phenobarbitone and soluble phenytoin. It has to be remembered that the therapeutic dose of soluble phenytoin is only narrowly separated from the toxic dose; and the preference for mysoline, a drug of low toxicity, evinced by these 15% of patients is not likely to be merely fanciful.

TABLE II—RESULTS OF TREATMENT OF GRAND MAL WITH MYSOLINE

Degree of improvement	Percentage of patients
100 %	3
75 %	10
50 %	15
25 %	7
No improvement in incidence of fits, but "feeling better"	15
Treatment discontinued	50

Of the 29 patients still being treated 20 are taking mysoline only; 2 are having mysoline plus malidone (because of petit mal); and the remaining 7 are having mysoline plus soluble phenytoin.

A slighter improvement in the incidence of petit mal was also recorded. In all, 23% of patients have experienced an average reduction of just over a half of their petit-mal attacks. A reduction of grand-mal attacks was not necessarily accompanied by a corresponding improvement in the petit-mal incidence, or vice versa.

The only patient in the series with psychomotor attacks has shown great improvement.

As has been mentioned, all 58 patients originally selected for treatment had, at different times, had full doses of other anticonvulsants or combinations of them. They were, in fact, the worst cases of idiopathic epilepsy from the point of view of treatment; and much surprise and gratification were evoked by the fact that as many as 20 of them were helped by mysoline alone. Less severe cases of epilepsy might well respond much more satisfactorily.

SUMMARY

Of 58 epileptics treated for grand mal with mysoline for fifteen months 50% derived benefit.

Most of the patients complained of drowsiness for a day or two. In 8 cases persistence of this symptom necessitated the withdrawal of the drug. Apart from this, toxic symptoms and signs were few and transitory.

Petit-mal attacks were reduced by half in 23% of the cases. One patient with psychomotor attacks has shown great improvement.

The Imperial Chemical (Pharmaceuticals) Ltd. supplied the mysoline.

Annotations

MISDIAGNOSIS

A GREAT proportion of road accidents are due wholly or mainly to hurry and lack of care; only a few are unavoidable. Similarly, in diagnosis most mistakes can be attributed to the same two causes. It is old teaching that incomplete physical examination is the most important cause of misdiagnoses, and it is probable that lack of care is more often a factor than lack of knowledge. Present day opinion is perhaps tending more than ever to stress the value of a detailed history with full laboratory and other investigations, and to belittle the significance of physical signs. What, say many, is the value of the stethoscope in the diagnosis of early pulmonary tuberculosis when radiography has shown that it alone can detect the really early stages of this disease? True, replies the clinician, but radiography is not always available or of high standard, and therefore it cannot replace clinical examination. It is certainly a just demand of the general practitioner that chest radiography should be available to him directly, without the need for hospital outpatient or dispensary consultation. At the same time, the quality of the radiograph and the skill with which it is interpreted must be of high standard, or errors may easily be increased. Laboratory investigations, too, if used as a substitute for clinical examination, may have dangerous sequelæ; results are not always known before the patient has either died or recovered, and not uncommonly they are equivocal. Free access to laboratory diagnosis is not without some serious drawbacks, for it is not always realised how big the variations may be between different laboratories in the estimation of such things as, say, the blood-urea.[1] There is often a tendency to discard strong clinical evidence because of a negative laboratory report, just as an X ray finding is sometimes too easily accepted to the exclusion of a clinical diagnosis. Certainly many peptic ulcers are missed because a typical clinical history is at once discounted when the radiologist reports "no ulcer seen."

Mistakes are also very likely to arise when a diagnosis is made on the response to some special form of treatment. Thus, when the histidine treatment of peptic ulcer was in vogue it became fairly widely accepted that a dyspepsia was not due to an ulcer if it did not clear up under histidine injections—a disastrous conclusion. This type of error—diagnosis *ex juvantibus*, as Prof M Bürger terms it in a recent book[2]—is matched by diagnosis *e nocentibus*, in which worsening under a special treatment is taken as evidence for a particular diagnosis. Both are subject to many fallacies.

In recent years, both the accuracy of diagnosis and the stage at which it is made have become more important, largely owing to advances in therapy, and in particular to the rapidly enlarging field of surgical treatment. Once it was perhaps of mainly academic interest to detect, for instance, the exact type of a congenital heart lesion, or a mitral stenosis at its early stage; but it is now a matter of surgical urgency. Mistakes in diagnosis must, of course, be judged in great degree by their effect on treatment, and too much emphasis ought not to be laid on diagnosis as an end in itself. Little practical harm, for example, may be done if a leather-bottle stomach is missed in its early stages, since its growth may be slow, pain may be slight, and prospects of radical surgical cure at any stage are bad. But the public—perhaps rightly—will not appreciate such distinctions, and there is no doubt that the layman is less tolerant today of diagnostic failures than he was in the past. So much, indeed, is this the case that the fear of medico-legal proceedings is becoming a problem of very serious import in doctors' minds.[3] The young casualty officer threatened with a law case soon spreads alarm among his newly qualified friends, and it is possible that increasing difficulty may arise in finding young men willing to accept clinical responsibility unless they are encouraged and supported, more than has sometimes been the case, by their seniors and more experienced colleagues.

Bürger describes some of these difficulties in diagnosis, basing his discussion of them on 170 cases which at post-mortem examination were found to have been wrongly diagnosed. He writes clearly and with wisdom of these "failures," dividing them into different categories, but in every case posing five direct questions to the clinician who has been mistaken: (1) was a thorough physical examination of the patient undertaken? (2) were diagnostic investigations carried out—and which? (3) was the history properly assessed? (4) were the signs correctly evaluated? (5) were there superadded symptoms obscuring the diagnosis?

It might be a good rule for clinicians, whenever they make a mistake, to ask themselves these same five questions, even though they need not necessarily hold themselves equally to blame in every case if the answers are "no."

THE INCONTINENT WOMAN PATIENT

INCONTINENCE of urine is troublesome for both nurse and patient, tiring the one and humbling the other. One of the best achievements of modern geriatrics has been to show that many patients incontinent after a stroke can, if they are given training, recover sphincter control. Nevertheless there will always be a proportion who are unable to respond to such training. The men among them can usually use a bottle, and so protect their bedding; but women are not so fortunate, and there are still hospitals where the disagreeable task of sluicing the wetted sheets before sending them to the laundry is added to the already heavy assignment of the nurses. Any device which would reduce this burden seems worth trying, and the suggestion has lately been made to us that cushions of sphagnum moss, which could be thrown away after use, would not only protect bed linen, but would add greatly to the comfort of these patients.

Sphagnum was used on a large scale in the 1914–18 war, and its virtues were much discussed at the time; but when, with the coming of peace, the need for absorbent dressings diminished, sphagnum was allowed to drop out of use. This seems a pity, for its absorptive powers are remarkable, far in excess of those of cotton wool; and it grows so abundantly on moors throughout the country that its cost need only be trifling. During the late war we drew attention to its value,[4] and noted that methods of preparing it had advanced considerably.[5]

Botanically, sphagnum lies between the true mosses and the liverworts, and its large cells, perforated with small pores, absorb fluid rapidly and act as reservoir. It is much more efficient mechanically than cotton wool, which consists of cellulose tubes of small diameter, usually collapsed and twisted by drying, and so incapable of filling by capillary attraction like the moss cells. It grows in great profusion, and is so easily recognised that in the 1914–18 war it was collected by school children. But it is heavy when wet, and the gatherer must resist the impulse to wring out the water and so damage the cells; only gentle squeezing is permissible. The moss should be spread out to dry in an attic or outhouse; for though oven drying is quicker it makes the moss brittle. Foreign bodies such as twigs and dead leaves should be picked out and the dry moss packed in muslin bags

PERINEAL TESTIS

JOHN C. N. WAKELEY
M.B. Lond.
LECTURER IN ANATOMY, KING'S COLLEGE, LONDON

PERINEAL testis was first described by John Hunter in 1786, when he reported 2 cases and also gave his classical description of the gubernaculum, which he believed was responsible for the descent of the testis.

Ricord (1843) reported 2 cases, and Vidal (1844) observed 2 more. Curling (1856) was the first to operate for this condition, on an infant aged 4 weeks which later died of sepsis. Partridge (1858) and Adams (1871) were the next to operate, both with fatal results due to sepsis. The first successful operation was done by Annandale (1879).

Weinberger (1899) reported that 74 cases had been published, Klein (1906) found 81, and Campbell (1936) brought the number up to 102. Jones and Lieberthal (1938), Cecil (1947), and Wattenberg et al. (1949) each added 1 case.

I report here 3 more, bringing the total to 108 cases, and discuss the anatomical development giving rise to this condition.

CLASSIFICATION OF ECTOPIC TESTIS

The only mammals in which the testes are found in the scrotum at birth are man and the chimpanzee. In man, as is well known, the testis may not always reach the scrotum but may be arrested along its normal path of descent—the condition called cryptorchidism. If, however, the testis migrates from its normal channel of descent, it is known as an ectopic testis. This condition is very rare, but five types of ectopic testis have been described, of which perineal testis is one. The standard classification is as follows:

(1) *Interstitial.*—After the testis has left the external ring it passes upwards and laterally towards the anterior superior iliac spine and comes to rest on the aponeurosis of the external oblique muscle. This is the most common variety of ectopic testis.

(2) *Pubopenile.*—Here the testis passes out through the external inguinal ring and comes to lie on the base of the dorsum of the penis and the overlying os pubis. Only 6 cases have been recorded (Popow 1888, Poupart 1897, Forsyth 1924, Bernhard 1925, Kausch 1925, Kaufman 1943).

(3) *Femoral or Crural.*—Here the testis is found in the medial portion of the femoral triangle.

(4) *Transverse.*—Both testes descend in the same inguinal canal and are therefore found lying in the same side of the scrotum. Hertzler (1916) recorded 16 cases.

(5) *Perineal.*—The testis, having passed through the external inguinal ring, descends to the perineum and comes to lie near the ischial spine and is often attached to it.

An important feature from the surgeon's point of view emerges from the anatomical facts of these conditions. The spermatic cord of an ectopic testis is of a normal length, whereas in cryptorchidism it is shorter than usual.

DEVELOPMENT OF TESTIS

The testis develops in the genital fold on the medial side of the excretory apparatus. At first the genital gland lies in the upper part of the body cavity. It is often taught that the testis moves to the region of the iliac fossa, but it is now thought probable that there is no active descent but rather a degeneration of the cranial end of the gland and a growth at the caudal end, the two processes taking place pari passu, with the result that the testis occupies a lower position in the body cavity. At the seventh week of fœtal life the lower pole of the testis lies at the brim of the true pelvis.

The caudal end of the testis is attached to the mesonephric fold at the brim of the pelvis. Here the genital fold of mesenchyme condenses to form a cord composed of connective tissue and plain-muscle cells. This will form part of the gubernaculum, which corresponds to the ligament of the ovary in the female.

In the meantime the urogenital fold becomes connected to the anterior abdominal wall at the crista inguinalis. There is from the outset a compact cord of mesenchyme present in the crista long before the muscles of the abdominal wall are differentiated. When later this musculature begins to develop it grows round this cord, which is also a part of the gubernaculum. At the external oblique muscle this cord becomes continuous with a further mesenchymatous cord extending to the integument. Lastly a further mesenchymatous cord develops in the mesonephric fold, connecting the cord at the lower pole of the testis with that in the abdominal wall. A complete gubernaculum has now been formed extending from the testis to the scrotum (see figure).

John Hunter was the first to describe the gubernaculum, and in the opinion of McGregor (1929) his description is still the best. It is as follows:

> "The testicle is connected in a very particular manner with the parietes of the abdomen. This connection is by means of a substance which moves down from the lower end of the testis to the scrotum. At present I shall call it the ligament or gubernaculum testis, because it connects the testis with the scrotum and directs its course in its descent. It is of pyramidal form; its large bulbous head is upwards and fixed to the lower end of the testis and epididymis, and its lower slender extremity is lost in the cellular membrane of the scrotum. The upper part of this ligament is within the abdomen, before the psoas reaching from the testis to the groin, or to where the spermatic vessels begin to pass through the muscles. Here the ligament runs down into the scrotum precisely in the same manner as the spermatic vessels pass down in adult bodies and is there lost. It is hard to say what the structure or composition of this ligament may be. It is certainly vascular and fibrous, and the fibres run in the direction of the ligament itself. It is covered by the fibres of the cremaster or musculus testis, which is placed immediately behind the peritoneum. This is not easily ascertained in the human subject, but is very evident in other animals, more especially those where the testicles remain in the cavity of the abdomen after the animal is full grown" (Hunter 1786).

which can then be sterilised. Steam was used for this purpose in the 1914–18 war, but it reduces the absorptive power by hardening the walls of the cells. A later method, described in detail at the time,[6] was to impregnate the moss with corrosive sublimate. The bags were then usually flattened in a hydraulic press, the thin sheets thus produced being easier to pack and handle. The absorptive power of the moss, however, was impaired by the pressure; and it is best used in the form of loose pads. These should be peculiarly convenient for the use of the incontinent, and for patients without bedsores sterilisation of the moss should hardly be necessary. Cushions of sphagnum, capable of taking up 12–19 times their own weight in fluid, would not only reduce the work of the nurses, but would restore to patients some of the confidence and self-respect which lying in a wet bed, even for a few minutes at a time, so quickly destroys.

THE TREASURES OF BARTS

St Bartholomew's Hospital for its first four hundred years was an ecclesiastical institution, and for its second four hundred years a Royal Hospital administered by its own board of governors. Under the Act of July, 1946, it started a new career as part of the national hospital organisation; which seems to augur well for the durability of the National Health Service. In the splendid 18th century great hall was displayed last week an exhibition of fine portraits, ancient documents, prints, and archives, and as well as the superb 17th-century flagons, chalices, and patens of St Bartholomew's the Less, the parish church of that unique parish, the hospital. It is a collection that spans much of the story of medicine. The earliest document is a deed sealed in 1137 by Rahere, founder of the hospital and priory, and himself first prior and master of the hospital; his very bones lie just outside the precincts in his own priory church, St Bartholomew's the Great. A few centuries after he sealed it—some time between 1420 and 1468—Brother John Cok, the hospital renterer, sat down to copy exquisitely into his illuminated *Cartulary* all the deeds in the possession of the hospital in his time; and more than half of these original deeds are still in the hospital's care. How much he would have valued—if he had lived another hundred years to see it—the indenture signed and sealed by Henry VIII giving the hospital to the Mayor and Commonalty and Citizens of London and their successors for ever, for the relief of the "poor, aged, sick and impotent people . . ." The seals on ancient Royal documents are things to marvel at, so rich are they in design, so finely coloured and so very large—about as big as a Camembert cheese. St Bartholomew's has documents sealed by Edward II, Elizabeth I, Edward III, and a good many others. In this exhibition James I, in armour, mounted and waving his sword, gallops across a flowery mead, a hound at his side, and a Tudor rose at his back. Next to him Queen Victoria sits sedately bolt upright on a stout Victorian horse.

Thomas Vicary, William Harvey, Sir James Paget, and many other famous old Barts' men appear here; and the portraits of Percival Pott by Sir Joshua Reynolds and of John Abernethy by Sir Thomas Lawrence are national treasures, quite apart from their medical interest. Then there are prints showing the hospital in former times, Rowlandson's cartoon of Bartholomew Fair (which was still being held less than a century ago), and records of martyrdom in Smithfield market, just outside the hospital gates. From the last century bills and ward reports have survived, and records of patients—including the case of Elizabeth Brookes, who had led a seafaring life and been used to drink raw rum in the West Indies. Somehow she makes modern patients seem rather tame.

BRUSH AND PASTE

Some years ago a favourite slogan in dental propaganda was: Clean Teeth Do Not Decay. Much depends on what was meant by "clean," but the inference presumably was that brushing would ward off caries. This is not true, as any dental surgeon—and many patients—will admit. A patient with a mouth never touched by a brush, although he probably has gingivitis or perhaps pyorrhœa, may have caries free teeth, while another whose oral hygiene is beyond reproach may need conservative treatment every three months. Nevertheless, for æsthetic reasons if for no others, cleaning the teeth seems desirable—at any rate for civilised man, whose diet might have been designed to leave the maximum amount of debris on and around the teeth.

The practice of cleaning the teeth by mechanical means is not new. Hindu writings dating from about 400 years ago refer to the use of myrtle twigs[1] for this purpose—a method still used in some parts of the world, especially among Mohammedans. The bristle brush seems to have been introduced about 1640.[2] The earlier advertisements for these brushes often referred to them as gum brushes; "toothbrush" is a much newer appellation—and a worse one, since the brush can play a most useful part in massaging the gums. Now, however, one of the leading firms of brush manufacturers has adopted the term "mouthbrush," which, though sounding strange, at least indicates the brush's function.

Present day views on the shape and material of brushes are described by Bryan Wade,[3] who cites the results of a postal survey by a manufacturing company. The dental profession favour a medium-texture bristle (rather than nylon) brush set on either a bayonet-shaped or an angled handle. At least two smaller sizes of brush should be made for children, and all brushes should be narrow to avoid laceration of the buccal mucosa, which may result from enthusiastic application of a wide brush. A suggested maximum width is 9 mm. The dental profession's preference for bristle seems to have little rational foundation.[4] In experiments in which extracted teeth were brushed mechanically with water alone for the equivalent of thirty years' normal brushing, the teeth showed no macroscopic signs of wear with either a hard bristle or a medium nylon brush. When, however, a popular brand of dentifrice was used grooves appeared on the teeth after the equivalent of a year's brushing; there was no difference in depth between the grooves produced by nylon and those from bristle. The results of such an experiment in vitro cannot perhaps be applied clinically without reservation; but it seems fairly safe to assume that, while there is little to choose between bristle and nylon, the composition of dentifrice should be further investigated. Wade suggests that patients with gingival recession should be told to use plain white toilet soap rather than a proprietary dentifrice which may be abrasive. It has been suggested that nylon brushes may cause gingival recession, but there is no definite clinical evidence of this. In fact, patients with the troublesome condition of sensitive dentine at the cervical margin are often relieved of their pain by reasonably hard brushing. The reason is obscure, but it may be that keratinisation is induced by the friction of the brush.

Obviously, if a brush is to be used on the gums and teeth, it must be used intelligently: it is worse than useless to attack the teeth as if one were getting down to a dirty floor with a scrubbing brush—nor, for that matter, is the habit of a patient who used a well known brand of scouring powder to be recommended. For

NORMAL AND ABNORMAL DESCENT OF TESTIS

John Hunter's observations on migration of the testis and in the fœtus were numerous. He was of the opinion that respiration played no part in the descent of the testis, since the testis was usually in the scrotum before respiration began. Nor could descent of the testis be influenced by the cremaster muscle, since no such function was found in hedgehog or other quadrupeds. Hunter also thought that the effects of posture, abdominal pressure, and the pressure of respiration should be considered when the testis did not descend in fœtal life.

In 1841 Curling dissected out the inguinal canal and, drawing up the gubernaculum, traced three processes: (1) the external process, which was the broadest and connected to Poupart's ligament; (2) the middle portion, a long band of muscle-fibres which escape from the external inguinal ring to pass down into the bottom of the scrotum, there blending with the dartos muscle; and (3) the internal band, which passes inwards to become attached to the os pubis and the sheath of the rectus muscle (Curling 1856). He noted that the middle band of fibres soon become indistinct and waste away, although remnants are seen throughout life. These may be found during operations on the testis or after death: on pulling the testis from the scrotum, the lower part of the testis is firmly anchored to the bottom of the scrotum by a dense fibrous band. This band forms the middle band of fibres of the gubernaculum. Curling was of the opinion that the pull of the gubernaculum was the sole cause of the descent of the testis.

In 1887 Lockwood published his Hunterian lectures on the development and transition of the testis—normal and abnormal. After many dissections and much anatomical research he originated the theory of multiple gubernaculum tails. The attachments of these tails he enumerated in the order in which they seem to develop:

(1) The abdominal tail went to the aponeurosis of the external oblique muscle near the anterior superior iliac spine.

(2) The pubic tail went to the root of the penis. The saphenous tail made its way down into the medial side of the femoral triangle.

(4) The perineal tail passed down into the perineum and became attached to the ischial spine.

(5) The scrotal tail passed down into the bottom of the scrotum, where it blended with the dartos muscle.

Lockwood thought that the scrotal tail was the most highly developed, and therefore drew the testis down into the scrotum. If this tail were ill developed or absent, the testis might be drawn into an ectopic position by the other tails, and thus come to lie in the perineum. McGregor (1929) in his dissections was unable to find any of Lockwood's divisions of the gubernaculum, and Sonneland (1924) denied the existence of any evidence of tails either anatomical or embryological.

McGregor (1929) described the "third inguinal ring." His research was stimulated by the work of Burdick and Coley (1926), who attributed ectopia of the testis to passage of the testis under Scarpa's fascia. McGregor undertook new dissections of the region and concluded that ectopia of the testis was due to the development or lack of development of the various fascial planes, which created congenital fascial ridges, pockets, and anomalies, forming the third inguinal ring. This ring could easily be felt clinically and was the gateway from the inguinal canal to the scrotum.

Various workers felt that, although the anatomical arrangements described might explain why the testis became ectopic, they did not explain the underlying cause of the movement in the first instance. Sebileau and Descomps (1916) and Klein (1906) therefore studied the problem from the viewpoint of phylogenic and ontogenic development. In the camel and the otter the testes remain inguinal, whereas in the whale, the elephant, the rhinoceros, and other pachyderms they remain inside the abdomen; in swine, wild boars, civet cats, and other carnivores the testes are perineal; and in the kangaroo they are pubopenile. These workers did not find any animals in which the testes were interstitial or femoral.

From these studies it is clear that most of the ectopic misplacements of the testis in man have a counterpart in the lower animals. Up to now, in spite of all the research on this subject, nobody has yet been able to state categorically the mechanism causing descent of the testes. There seem to be two processes influencing its descent:

(1) The formation of the gubernaculum very early in fœtal life—even before the development of the abdominal musculature—creates a pathway for the testis to follow through the forming inguinal canal into the scrotum. Whether or not the gubernaculum actively contracts and pulls the testis down into the scrotum remains to be proved.

(2) There seems to be some evidence that hormones play a part in descent of the testes.

CLINICAL PICTURE OF PERINEAL TESTIS

The patient always presents with a swelling in the perineum. In every case this lies behind the root of the scrotum and in front of the anus, and is lateral to the median raphe of the scrotum. The skin over the scrotum appears perfectly normal, and the swelling can be slipped around in any direction. The scrotum is always asymmetrical; the side containing a testis appears normal, whereas on the side of the perineal testis the scrotum is rudimentary.

CASE-RECORDS

Case 1.—A boy, aged 3 years, was seen at the Belgrave Hospital for Children, on May 6, 1923, complaining of pain in the perineum. A perineal testis was found, and the right side of the scrotum was empty.

Operation.—Through an inguinal incision the ectopic testis was delivered from the perineum and transferred to the right side of the scrotum. The testis was made to descend to the bottom of the scrotum through a passage made for it with the finger, the spermatic cord being sufficiently long to allow this. The wound was closed without drainage. Recovery was uneventful.

Follow-up.—The child was seen again in 1924, when the testis appeared normal in every respect and was equal in size to the left testis.

Case 2.—A boy, aged 20 months, was admitted to the Belgrave Hospital on Jan. 16, 1930, because of a small swelling in the left side of the perineum. The left side of the scrotum was empty. The swelling was as big as a small marble and freely movable upwards.

Operation.—An inguinal incision was made and the spermatic cord isolated at the external abdominal ring. By gentle traction the ectopic testis was delivered and passed into the left side of the scrotum. The wound was closed without drainage, and recovery was uneventful.

Follow-up.—When the boy was seen five years later, the testis appeared normal.

Case 3.—A boy, aged 1 month, was brought to the Belgrave Hospital on Jan. 17, 1952, because of a swelling in the right side of the perineum. The right side of the scrotum was empty. The swelling, which was about the size of a small marble, was freely movable upwards.

Operation.—A small right inguinal incision was made, and the testis was delivered into the wound from the perineum by gentle traction on the cord. A small hydrocele was found and incised. The testis was drawn into the right side of the scrotum, to which it was fixed with stitches. The wound was closed without drainage. Recovery was uneventful, and the testis appeared completely normal a month after the operation.

SUMMARY

Three cases of perineal testis are described. The anatomical development of the testis and gubernaculum children especially, there is much to be said in favour of eating a raw apple after meals, and, until the child is old enough to manage a brush properly, the teeth can be kept free of food debris by lint or cotton-wool wrapped round the finger.

PRIMITIVE POISONS

PRIMITIVE races put their poisons to three uses: they apply them to weapons for use in the chase and in war, they use them with intent to kill or annoy those whom they dislike, and they find them particularly suited to judicial ordeal, for trial and execution are simultaneous. The investigation of these poisons is complicated by the fact that few are simple preparations: numerous other ingredients, sometimes as many as twenty, are added for purposes of magic, or to obtain the ideal consistence for anointing weapons and to ensure rapid absorption. Many of these additions are virtually inactive pharmacologically, although potent poisons are sometimes mixed, as when brucine, opium, or arsenic are added to the already deadly sap of the Upas tree.[1]

In ancient Europe the poisons of choice were probably hemlock, the active principle of which, conine, has nicotine-like properties, or *Datura stramonium*, which was used to inspire the pythoness of the Delphian oracle. As arrow poisons, aconite, hellebore, and yew were used; the active principles are aconitine, protoveratrine, and taxine, which slay by cardiac and medullary depression. Various concoctions of viper venom or putrefied human blood were favoured here and there.[2] In Africa very many plants have been used as sources of poison, the chief being those containing strophanthin-like glycosides and strychnine or brucine. In some places today fowls or dogs have taken the place of human litigants and so the trial by ordeal has lost some of its drama.[2 3] Less widely used as weapon poisons are sources of eserine, croton (producing hæmolysis, nephritis, and respiratory depression), the sap of various Euphorbias (severe local inflammation with tissue necrosis), cobra venom (hæmolysis, curariform paralysis, and central depression), and various other snake venoms and extracts of poisonous larvæ, centipedes, and decomposing flesh, human and animal. Incidentally, cobra venom has in recent times been the subject of an unsuccessful clinical trial as an analgesic.[4]

Sometimes in Dahomey the true judicial ordeal is falsified when poison is given to one party only, whose guilt has been previously decided by the witch doctor, who may have been influenced by gifts made before the ceremony. In these circumstances, "tout à coup, l'un des deux plaideurs meurt en quelques instants, frappé en apparence par la colere d'un dieu vengeur et, en réalité, par une énorme dose de boundou" (strychnine).[3]

In Madagascar arrow poisons have never been used, but judicial ordeal was popular, and a strophanthin-like poison from *Tanghinia venenifera*, the "ordeal tree," was widely used. It is recorded that in one ordeal 6000 people died. In North-east Asia and Alaska arrows are poisoned by being left imbedded in a corpse, and extracts of various plants of the anemone family are used. These have general effects similar to aconitine and a local irritant action like cantharidin. In East and Central Asia weapons are poisoned with aconite, croton, various cadaveric extracts, and crushed spiders. In Indo-China the principal poisons are strophanthin-like, and are obtained from various species of strophanthus and from "the celebrated deadly Upas tree," *Antiaris toxicaria*,[1] the active principle of which is antiarin. Each tree has its owner who alone may exploit it.[5] It grows also in Malaya, Java, Sumatra, Borneo and elsewhere.[1 2] An arrow poison in use in Borneo today has recently been examined[6] and found to have properties similar to antiarin, although its botanical origin is uncertain. Ordeal poisons are not used in Asia but for criminal purposes there are hyoscyamus and abrin. In Malaya and in the islands to the south and east strophanthin-like and convulsant poisons (strychnine and picrotoxin) are popular. Derris, the common garden insecticide, is used on weapons and for poisoning fish; it is relatively nonpoisonous to man,[1] but it causes vomiting, convulsions, and death by respiratory depression in animals.[7]

In the New Hebrides bacteriological warfare was developed: arrows were smeared with material infected with tetanus bacilli and vibrios, the latter, if fresh, causing death in 12–15 hours. Severe sepsis and gas gangrene due to accidental contamination of the arrows are, of course, common in all parts of the world. Various other poisons, similar to those used in Malaya, are also available in the Pacific Islands. The greater part of North America is without useful weapon poisons, but crushed snakes, putrefied deer liver, menstrual blood and rattlesnake venom were used here and there, chiefly by the Indians in the south-west. Central America has no effective weapon poisons, but South America has the best known of all arrow poisons, curare, and animal putrefactive products and venoms are also used. Inorganic poisons are little used by primitive peoples except for criminal purposes. Arsenic is probably the most wide spread and has been used on the Malay kris, as well as in food.

POOR MAN'S TISSUE CULTURE

FEW pathologists engaged in the routine diagnosis of morbid conditions are familiar with the microscopical appearances of living cells. The techniques of fixation and staining are well established, and especially convenient in these days when much work has to be delegated to technicians. Furthermore the apparatus for the newer techniques is seldom available outside research centres. Pulvertaft and Jayne,[8] however, have described a technique for examining cells in exudates which is suitable for routine use and calls for no special apparatus beyond a phase-contrast *microscope* and suitable illumination.

After two hours' incubation on serum agar the cells, spherical at first, begin to move and show their several characteristics. All are capable of throwing out pseudopods and may show motion of some kind for as long as fourteen days. Polymorphs, lymphocytes, and endothelial cells can be distinguished, and often malignant tissue can be clearly differentiated. The cells of malignant tissue are often arranged in three-dimensional masses and even form acini—a feature never found in non-malignant exudates. A few of the cells scraped from malignant tumours may survive and even divide by mitosis, but Pulvertaft and Jayne do not consider that malignancy can be established by studying individual cells. This technique of cell culture on serum agar is particularly well suited to the investigation of exudates for diagnostic purposes, but it has other applications. Since cells remain alive and motile for days, they may be submitted to pharmacological and other tests, or the effects of radiation may be studied. In addition to exudates, scrapings from malignant tumours and their metastases can yield suitable material for study.

This kind of work is clearly in its infancy, but now would seem the moment for enterprising pathologists to test its value in diagnosis.

POSITIVE-PRESSURE HOOD AND SPLIT FRONT FOR THE BOTH RESPIRATOR

A. B. CHRISTIE
M.A., M.D. Aberd., D.P.H., D.C.H.
PHYSICIAN-SUPERINTENDENT, FAZAKERLEY HOSPITAL, LIVERPOOL

J. R. ESPLEN
M.R.C.S., D.A.
CONSULTANT ANÆSTHETIST, AINTREE HOSPITAL, LIVERPOOL

CONSIDERABLE distress is experienced by many patients on their removal from the "iron lung," or cabinet respirator, for nursing purposes; and, though a skilful operator can provide efficient ventilation for the occasion with a mask and positive pressure, the procedure is uncomfortable for the patient and can only be used for short periods.

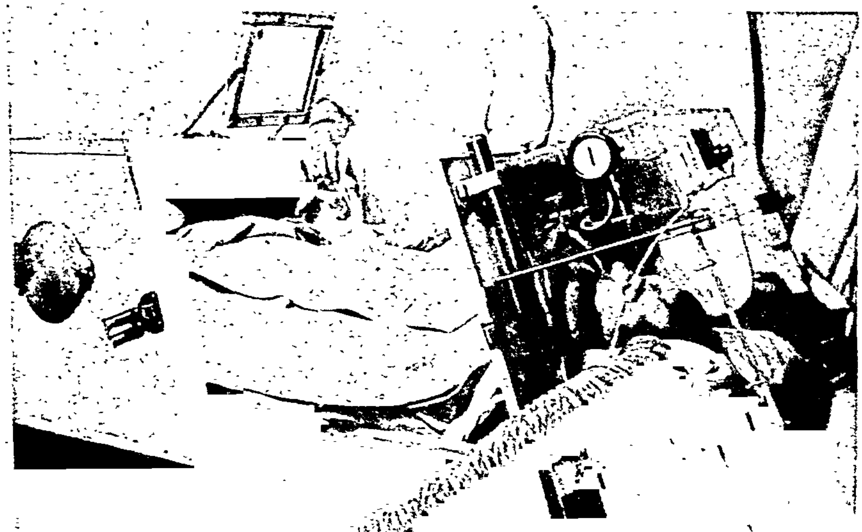

Fig. 1—Positive-pressure hood in action, with cabinet respirator opened. Note flap-valve to right of patient's head.

In our efforts to discover a more satisfactory form of ventilation we have relied on the resources of the hospital workshops and have been limited to the use of materials of ordinary availability.

The pressure-hood described here has been used for four months with excellent results. The principle of the apparatus is not new, but the hood has been of such obvious benefit to patient and nurses that we feel that some account of the appliance should be given now before the start of the poliomyelitis season. It provides comfortable respiration by positive-pressure inflation of the lungs, and enables a patient to be removed from the cabinet respirator for an indefinite period; in practice we have used the hood for two hours at a time.

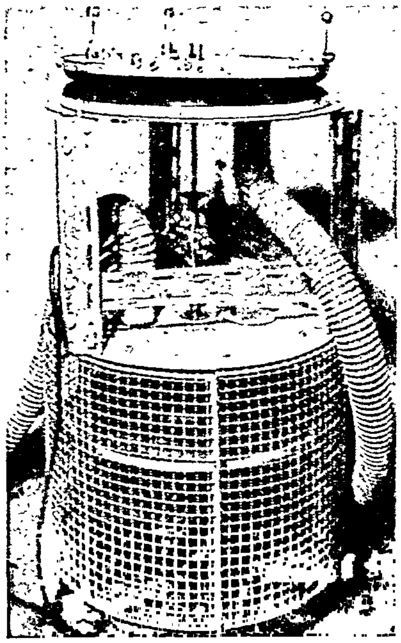

Fig. 2—Two Both bellows linked together to develop positive hood pressures and negative cabinet pressures in synchrony.

THE HOOD

The hood (fig. 1) is an open box-shaped structure made from $^3/_8$-in. 'Perspex' sheeting. In use the open side of the box is applied to the head-piece of the Both respirator to enclose the patient's head, and the air-pressure in the hood is then raised and lowered by connecting it to a Both bellows.

The over-all dimensions of the two irregular quadrangles which form the sides of the hood are 21·5 × 14·5 × 21·75 × 12·75 in., and the width of the hood is 17·75 in. The sheets of material are held together with screws and perspex cement.

In the side of the hood to the right of the patient is a circular opening, 4·5 in. in diameter, covered by a rubber flap, which admits air to the hood during the suction phase of the bellows and prevents air from escaping during the pressure phase. On the same side, in the lower right-hand corner of the hood, is a metal tube 6 in. long and 0·5 in. in diameter through which a rubber tube may be passed to convey oxygen to a nasal catheter or a mask

On the left side of the box are fittings for attaching a pressure gauge and the air-hose of a Both bellows.

The two clamps which hold the hood in position are made from steel rods 0·25 in. in diameter. Each rod is bent

JUNIOR MEDICAL STAFFING IN HOSPITALS

FIVE YEARS OF FAMINE

T W Hurst, F H A, A C I S, GROUP SECRETARY
C B Linfoot, F H A, A C I S, DEPUTY SECRETARY
T K Woodhouse, ADMINISTRATIVE ASSISTANT
WIGAN AND LEIGH HOSPITAL MANAGEMENT COMMITTEE

Difficulties in providing hospitals with junior medical staff were already serious before the National Health Service was established It was hoped that, with the new Act, the situation would improve, but after nearly five years the problem seems to be as far from solution as ever

EXTENT OF SHORTAGE

Some measure of the great increase in the number of posts for junior medical staff may be obtained by taking figures for a non teaching group of hospitals in an industrial area Junior medical staff (i e , equivalent grades below senior registrar) taken over in July, 1948, at voluntary and municipal hospitals in that group numbered 10 The latest establishment figure for similar grades is 30 A fair proportion of these 30 posts remain unfilled, and perusal of the advertisement columns of the medical journals shows that many other hospital management committees are repeatedly advertising posts of this type with no apparent success We understand that a committee recently spent over £100 in advertising one post which did not attract a single applicant

As the necessary pre-war statistics do not exist, it is impossible to make an exact comparison between the position in pre nationalisation days and today Prof W H Wynn,[1] however, has quoted figures showing that, in 1950 there were 5824 junior medical posts, of which 1622 were in teaching hospitals A rough estimate puts the number of junior medical posts in non-teaching hospitals before nationalisation at about 1500

CAUSES OF SHORTAGE

Perhaps the most obvious cause of the present shortage was the sudden transition to a system which provided "free" medical, hospital, and health services for all, with consequent increased demands on these services

Formerly the smaller non-teaching hospitals were mostly staffed by a nucleus of residents, supplemented by leading medical practitioners of the area, who served as honorary physicians and surgeons In this way, general practitioners contributed their share to the hospital services, but this arrangement has now ceased in all but a few small general-practitioner hospitals for which special provision is made in the new service

With the appointment of separate hospital consultants and subordinate medical staffs, contracts of service have been related to more reasonable working hours than were customary in the medical profession in past years No longer is the doctor expected to work the long hours which previously gave him little opportunity for relaxation and study Like other sections of the employed population, he is entitled to a reasonable amount of leisure time

A further important factor is the expansion of the hospital service A survey of British Health Services[2] shows that in 1936 there were 2795 hospitals with a total of 410,829 beds In 1950, total beds in hospitals of all classes were 504,321—an increase of 93,492

The shortage of hospital staff may also be aggravated by

1. (1) A desire on the part of general practitioners to reduce their working hours to a reasonable level
2. (2) A scarcity of general practitioners in certain areas, which makes it difficult for them to give the necessary attention and treatment to their patients and leads them to refer patients to hospital whom they would otherwise have treated themselves

On the other hand, an increase of the proportion of doctors in general practice (as envisaged in the Working Party's recommendations) might not, on balance, help the hospitals, for it would reduce the number of doctors available for the hospital service Again, the public now tends to demand attention at consultant level, thus preventing the general practitioner from carrying out his normal duties

Continuing advances in medical science are resulting in more elaborate forms of treatment and creating new branches of medicine which require separate staff, and this development contributes towards present day shortages Since nationalisation, lack of funds has obliged hospital authorities to retain small hospital units which in many instances are not economic in providing the increased services required of them Much time must be wasted by medical staffs travelling between hospitals of this type—time which would be spent more profitably if larger hospital units were established

There must be many other possible reasons for the present difficulties in providing medical staff for the hospitals We need mention only the following contributory causes

(a) Insufficient recruitment to the medical profession.

In England and Wales 2104 posts at 456 hospitals have been approved as preregistration house officer posts under the Medical Act, 1950 In 1951 there were 1531 registrations with the General Medical Council, which suggests a 25% deficiency between supply and demand

(b) Employment of doctors on non clinical duties—e g administrative medical staff employed by Ministries regional hospital boards local authority health services, marine services, and industry

(c) Call up of doctors for military service

The Under Secretary of State for War stated recently that there were 1550 doctors in the Army, apart from the other Services

(d) Reduction in supply of doctors from other countries (e g , refugees)

POSSIBLE REMEDIES

It seems certain that doctors will not go back to the earlier unsatisfactory conditions of long working hours, nor should they be expected to do so Similarly, it is unreasonable to expect a hospital doctor to participate in various different kinds of specialist work—any more than we ask a plumber to do the work of a joiner It becomes necessary, then, to inquire

(a) Can the number of patients now attending hospitals be reduced ? Or do the existing numbers represent a more or less permanent demand upon the hospital service ?

(b) Have the hospital services developed to such a stage that the country cannot afford further expansion ? The advances of medical science make it impossible for such services to remain static

Any reduction in the demand on the hospital service is likely to be achieved only by placing more work on the shoulders of general practitioners The burden borne by practitioners might in turn have to be lightened by discouraging patients from making unreasonable demands upon the services which are now "free" to all In time it may be possible to reduce numbers by instructing the public more intensively in preventive medicine and by

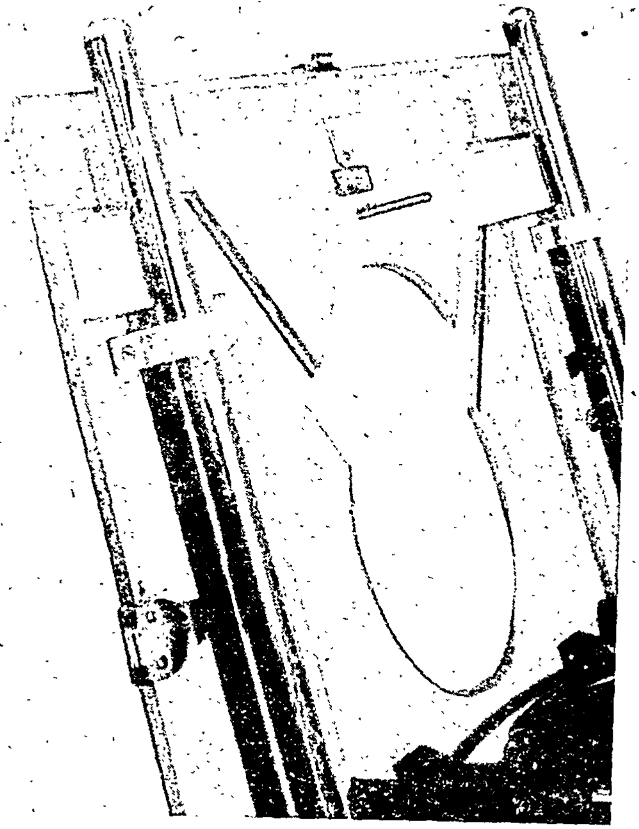

Fig. 3—Split front open.

to a right-angle about 1 in. from one end, and the bent-down ends fit into sockets secured to the respirator head-piece. The rods can be removed when the hood is not in use. Their free ends pass through slotted lugs, bolted to the back of the hood, and are threaded to carry wing nuts which can be tightened against the lugs. The lower edge of the hood rests on a wooden batten screwed to the head-piece of the respirator below its head-rest. The batten forms a shelf which takes most of the weight and helps to keep the hood in position.

The union between hood and respirator is made airtight by applying strips of adhesive ‘ Sorbo ’ rubber to the respirator head-piece along its lines of contact with the hood.

Our patient spent alternate periods of two hours in the hood and cabinet respirator, and an interesting point to us was his decided preference for hood ventilation when he was not feeling too well. It was our impression that the positive-pressure technique provided better oxygenation and produced a type of chest movement different from that produced by the cabinet respirator, the upper lobes of the lungs appearing to fill first with the positive-pressure method.

Whether the hood affords the patient any protection against droplet infection is not known, but it seems reasonable to suppose that it may do so.

The size and transparency of the hood, and the air-flow over the face, from the bellows during the pressure phase and from the atmosphere during the suction phase, were other features of the apparatus appreciated by the patient.

VENTILATION

The pressures used ranged from 0·5 cm. H_2O below atmospheric pressure to 12·0–20·0 cm. H_2O above atmospheric pressure. Pressure effects on the ears were not noticed below a pressure of 20·0 cm. H_2O, but higher pressures can produce earache. There was no complaint of flatulence due to swallowing air, despite the fact that drinks were taken freely, through a long feeding-tube, while the hood was in use.

Occasionally we combined hood and cabinet ventilation, providing a positive pressure in the hood and negative pressure in the cabinet simultaneously. Th patient's comment on this form of respiration was tha it made breathing “ too easy ” and abolished his natura urge to inspire. This method produces satisfactor *ventilation* with mean pressures close to the atmospheri level.

Fig. 2 shows two bellows linked together to develo positive hood pressures and negative cabinet pressure in sychrony. With the double bellows both hood an cabinet are always ready for use and the change-ove from one form of ventilation to the other is simplified. We suggest that this apparatus affords facilities fo studying some of the possible ways of applying negative and positive pressure to the chest; we agree with Ritchie Russell (1952) that these have not been fully explored.

COMMUNICATION

A disadvantage of the hood is that the patient in the hood cannot hear or speak to his nurse. Since our patient was in the hood for two or more hours at a time, we fitted a small microphone and speaker inside it and overcame the difficulty in that way. This device also enabled him to enjoy radio and television programmes, the screen for the latter being reflected in a mirror mounted on the cabinet.

CONTRA-INDICATIONS

The hood must not be used in unsuitable cases, because there is a danger that vomitus or secretions collecting in the pharynx may be forced into the airway before they can be removed. In such an emergency the nurse can reach the patient's pharynx by inserting her hand through the flap-valve opening. In doing this her arm will of course hold open the flap and interrupt inflation.

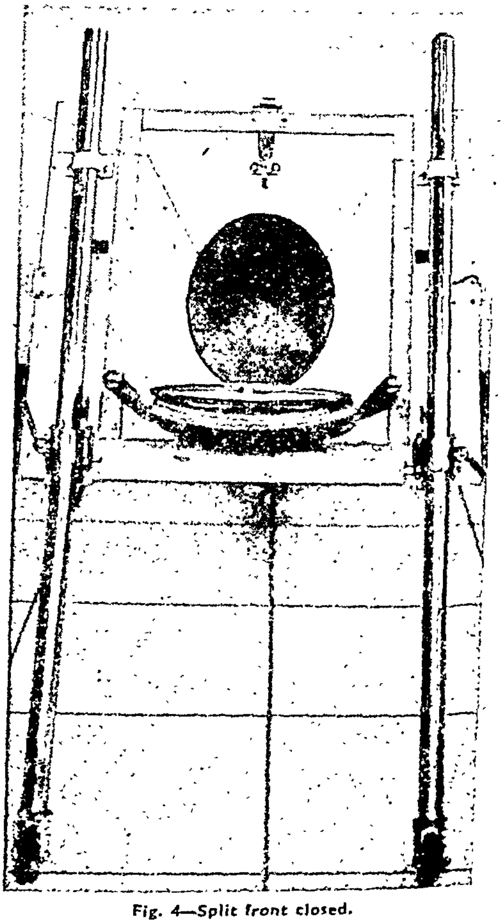

Fig. 4—Split front closed.

so greatly improving methods of treatment that patients will require less hospital care But if for the present we are to regard the demand for hospital treatment as unalterable, we must consider what further economies in medical man-power can be made The following possibilities suggest themselves

1 Train non medical technical staff to carry out preliminary investigations under medical instructions and to arrange for routine test investigations of new patients—e g , electrocardiograms, test meals, barium meals
2 Erect health centres as quickly as possible By saving the time of general practitioners, this may enable them to give some help in hospitals Alternatively, adopt some other means of economising in the use of general practitioners
3 Enlarge the medical schools and encourage more students to train as doctors
4 Require doctors to work in hospital for a period longer than the year prescribed under the Medical Act, 1950, and restrict the entry of doctors to non clinical posts which seem to have lesser claims on the medical profession
5 Encourage students or qualified doctors from abroad to take up medical work in this country
6 Create more full time consultant posts to replace some of the part time consultant appointments This would enable more work by consultant staffs to be done in the hospitals
7 Redistribute specialised beds in existing hospitals so as to avoid unnecessary travelling between hospitals in the various groups

When money is to be had for the purpose, the building of larger hospital units would result in a saving of medical man-power

If it proves possible to re educate the public in the use of the health services, some assistance with hospital work should be obtainable from doctors now employed in general practice Already many hospitals are using practitioners as part-time clinical assistants, and this arrangement might be extended, especially in connection with duties in casualty departments where the greatest difficulty is experienced

Another way of overcoming the staffing difficulties at a hospital where accident and acute cases are admitted might be to introduce a senior resident officer (of, say, junior consultant status) who would be appointed for several years and would be in line for promotion to consultant He should be given facilities for his family to reside with him at the hospital

Married women doctors not already engaged in practice might be encouraged to undertake part-time duties at hospitals, and retired doctors might also be prepared to do part-time work

Another possible method of overcoming the shortage in non-teaching hospitals might be to pay junior medical staff at a lower rate in teaching hospitals than in non-teaching hospitals On the other hand it might be possible to arrange for the transfer of junior medical staff from the teaching hospitals to the non-teaching hospitals for a period of service

CONCLUSION

In looking at recruitment to the medical profession attention must be paid to all the medical services concerned, not only the hospital service, and this is a matter which seems to call for discussions at high level between Government representatives, hospital authorities, local health authorities, executive councils, universities, the General Medical Council, and the representative medical organisations So that these discussions may achieve a useful result at the earliest possible date we suggest that the bodies mentioned should appoint representatives to attend a conference, with the Minister of Health in the chair, to discuss what should be done We recognise, of course, that before such a conference was held it would be necessary to obtain statistics showing the number of medical posts in hospital, general practice and so on, the number of qualified doctors, and the output of doctors from the universities It would also be desirable to have information about the man-power necessary for professions other than medicine, for industry, for the Armed Forces, and for other needs, and of the number of people available to do the work

SCOTLAND'S FIRST HEALTH CENTRE

THE first health centre in Scotland, opened by Mr James Stuart, the Secretary of State, on May 15, is an adventure in combined planning and administration and, as with similar adventures that are already under way in England,[1] its progress will be keenly watched

This centre, at Sighthill, a growing new suburb on the south west fringe of Edinburgh, was planned by the Department of Health for Scotland with the cooperation of Edinburgh Corporation and the good will of the local medical committee It contains suites for six general practitioners along with a pharmacy, a laboratory, and space for an X ray department, four dental surgeries, accommodation for infant-welfare and school health service clinics, and a gymnasium and a physiotherapist's room The building is also to be the headquarters of the health visitors and district nurses working in the area At present it serves a population of 10,000–12,000

DESIGN AND FUNCTION

Architects are a frustrated professional group, for since 1939 they have had little chance to show their paces The housing programme that has gone forward since the end of the war has provided scant opportunity for initiative, and only occasionally, as in the Festival of Britain, have the public been enabled to see how the profession's views have been shaping during its enforced quietude At Sighthill the architects of the Department of Health [2] have had the first chance in years of stepping out, it is little wonder that they show themselves mettlesome For a building of this sort, the centre is exceptional in that the architectural team has, subject to the general requirements, had a free rein both in designing the building and in choosing the furnishings The mixed array of coachmen can now congratulate themselves on their forbearance

Initially the Department had to choose between a small and relatively inexpensive centre, which might prove inadequate, and a more elaborate one that might turn out to be over large for the demands on it The choice fell on the second of these options both the number and the size of the rooms is large (the floor area totals some 35,000 square feet), and the cost, with equipment, is about £160,000

General Description

The building (fig 1) is in the form of a hollow square of one storey, except for one side where a second storey houses the dental surgeries and staff rooms It is built of concrete brick (clay is scarce in Scotland) with a prefabricated roof of copper on fibre The wings could be extended, and internal flexibility is assured by a 4 ft 9 in module The partition walls are of formed slag concrete blocks, these have no weight bearing responsibilities and can thus be pulled down at will (The idea

[2] The architects were ROBERT GARDNER MEDWIN (chief architect) ROBERT MORTON (deputy chief architect for special buildings) JOHN OGILVIE and GEORGE LAWRENCE (senior architects responsible for development of design and supervision) ERIC HALL (assistant architect), and R. J WALKER D A MACGILLIVRAY, and R F A LAIDIE (assistants)

The hood can be removed from the respirator in a few seconds.

Four months after his introduction to the hood the patient had recovered sufficiently to be transferred to a cuirass respirator, but subsequently he developed a secondary infection from which he died. At necropsy his lungs showed no abnormal changes attributable to intermittent positive-pressure breathing.

SPLIT FRONT

A divided head-piece or "split front" (figs. 3 and 4) is a great advantage in cabinet respirators from the point of view both of patient and staff; such a divided head-piece can be used with or without the hood. Smith (1953) has described an excellent split front; the only advantage we claim for our head-piece is that it can be made for a few shillings in any hospital workshop. The existing front of the cabinet is removed, and a new split one is substituted. Both divisions are made from stout plywood. The sides of the detachable upper section move in metal runners extending upwards from the sides of the lower section to which they are fixed. The meeting edges of the upper and lower sections are tongued and grooved so that they interlock when they are brought together.

This split front is still a sloping front, and it remains difficult to nurse a patient in the prone position. We are testing a further simple modification which we hope will overcome this difficulty.

SUMMARY

A positive-pressure hood for use with the cabinet type of respirator is described.

This hood is a much more convenient method of ventilating patients than the positive-pressure mask. It was designed to ventilate the patient during nursing procedures, but we *found that it could be used for much* longer periods.

Ventilation with either alternative or combined positive and negative pressure can be provided easily, and we suggest that these methods should be further investigated.

A simple method of splitting the front of the Both respirator is described.

We are most grateful to the staff of the Fazakerley Group of Hospitals maintenance departments for their enthusiastic coöperation in this work and for their technical skill.

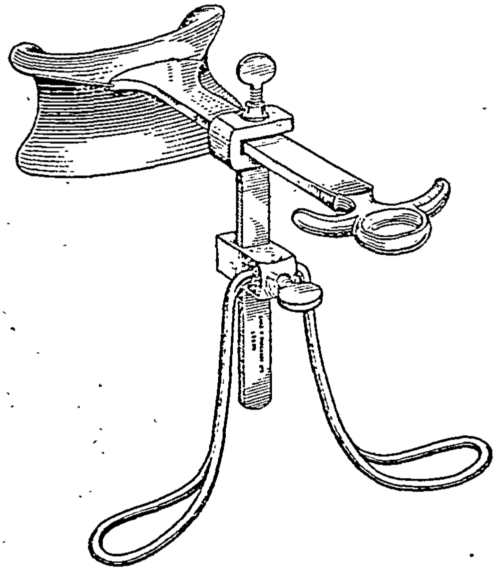
New Inventions

IMPROVED PELVIC STAND FOR DOYEN'S RETRACTOR

THIS stand is designed for placing between the patient's thighs and holds a Doyen's retractor firmly in place when exposure is needed for pelvic and bladder operations. This support does away with the cumbersome chain and weights previously employed and has several advantages over a similar type used in Birmingham. The illustrated design is smaller than the Birmingham pattern, is more easily sterilised, and has the advantage that the height of the jaws can be adjusted before insertion between the thighs, thus avoiding possible contamination from the skin in operations on fat women.



The stand is usually wrapped in a sterile towel before being placed between the thighs, to protect the vulva from any chance of bruising.

The original stands were kindly made for me by Messrs. Rolls Royce and I am indebted to Miss C. Jenner for the illustration. The instrument is now manufactured by Messrs. Chas. Thackray, of Leeds.

Reviews of Books

The Birmingham Hospitals Centre

STANLEY BARNES, M.D. Birm., F.R.C.P., LL.D., chairman of the executive board of the hospitals centre. Birmingham: Stanford & Mann. 1952. Pp. 144. 15*s*.

THIS is the story of the building of the centre now the pride of Birmingham and the envy of medical professors in this and other countries. Beginning with the origin of the scheme Professor Barnes describes the troubles met and overcome, the amalgamation of the General and the Queen's Hospitals, and the formation of a limited company to organise the finance, control the expenditure, and supervise the building. He tells of the completion of the great modern hospital now called "the Queen Elizabeth," of the Nuffield Nurses' Home, and of the Medical School, and of their baptism of fire in the second world war.

Among many generous donors and helpers three men stand pre-eminent in ability, devotion, and unwearying effort—the late Sir Charles Grant Robertson, then vice-chancellor of the university, Sir Harry Vincent, and Professor Barnes himself. It is regrettable that the scheme for a big hospital centre has in the last few years been in part spoilt. Land presented to the city for the purpose of hospital development has been used for the erection of some two hundred houses. Much of the detail makes fascinating reading and could have been expanded without loss of interest—the care taken to eliminate noise, the designing of a unit of 60 beds, the relative merits of a many-storeyed building in contrast to one built on the pavilion system. The book is a wonderful tribute to a great scheme triumphantly carried through and would have been a classic on the subject of hospital construction if more details had been given.

Human Blood Coagulation and its Disorders

ROSEMARY BIGGS, PH.D., M.D., graduate assistant, department of pathology; R. G. MACFARLANE, M.A., M.D., clinical pathologist, Radcliffe Infirmary, Oxford. Oxford: Blackwell Scientific Publications. 1953. Pp. 406. 32*s*. 6*d*.

A FULL-LENGTH monograph on this subject is timely. Dr. Biggs and Dr. Macfarlane justly point out that the subject and its complications can no longer be regarded with tolerant detachment by the ordinary doctor. "Blood coagulation research," they say, "has led to the discovery of a new vitamin, the recognition and treatment of a whole range of newly defined hæmorrhagic diatheses; it has raised problems in genetics and eugenics, introduced with all their attendant problems anticoagulant drugs for the treatment of thrombosis, and has been concerned with many subsidiary develop-

of putting up rather more temporary partitions was mooted but abandoned, mainly because of the need for noiselessness.) The ceilings—of insulation board topped with a quilt of glass wool—are reckoned to afford thermal and sound insulation. Heating is provided electrically from conduits embedded in the floors; the electricity is turned off at peak hours, at which times the rooms draw warmth from the heat stored in the fabric of the building.

The architects have relied on light, bold use of colour, and diversity, with a careful choice of furnishings, to give an air of richness and avert the chill institutional atmosphere. The many colours on the walls range through and sometimes, it seems, beyond the breadth of the rainbow; but the chocolate hue once revered by hospitals and public-houses is nowhere to be found. Throughout, the colours (except in the corridors, each of which is painted differently) are not restful: they are challenging, and occasionally the challenge may have overreached its mark, anyhow for those facing it every day—one doctor's room, for instance, has a greenish mustard carpet which draws the eyes by its repulsiveness. As to diversity, the walls of the main entrance hall are, in different sections, of stone, of painted plaster, and rough-cast; adjacent rooms rarely have the same colour motif; and in some rooms one wall differs from its three neighbours.

The Hall

The visitor approaching the main entrance (fig 2), at the junction of the administrative and general-practitioner wings, gains a sense of spaciousness. The surrounding gardens are unfenced; and to the left of the door is a large covered verandah with open fields beyond. Inside the door is a large stone-flagged hall, of which the commanding feature is a "suspended" staircase, winding up without visible means of support except for a spine of reinforced concrete.

This staircase has a strikingly light and gay air, which is heightened by the huge window behind it, stretching from floor to roof. To the left of this staircase, beside the entrance door, is the dispensary; and on the other side is the corridor of the administrative wing. To the right of this, facing the entrance, is an inviting-looking inquiry bureau with its large window framed in unpainted West African hardwood. (West African hardwoods recur in variety throughout the building.)

The visitor, turning to the right to enter the general-practitioners' wing, passes two further large windows. That on the right, or outer, side is double, with a wide interval between the two layers where plants are growing

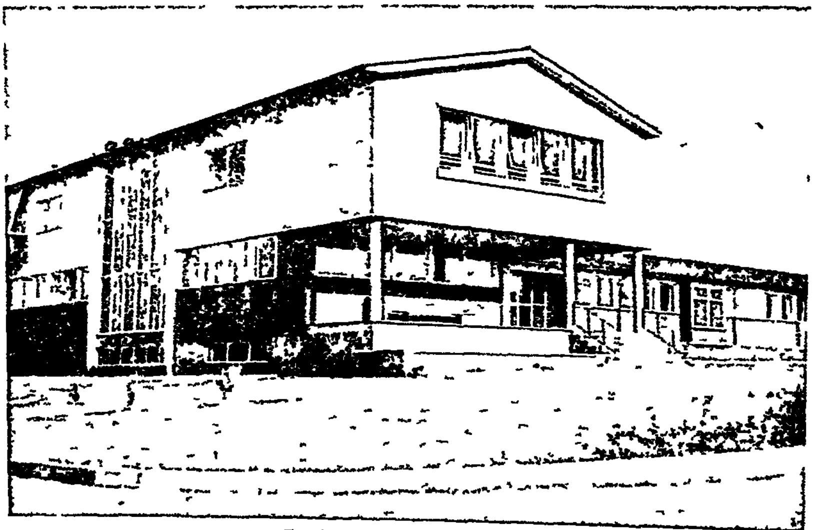

Fig 2—The main entrance

ments, such as synthetic resins and water repellent surfaces." But existing published work on this subject is bewildering: "The number of aliases, false clues, conflicting statements and fallacious deductions to be found there would arouse the envy of the most prolific writer of detective novels." The object of the authors is "to reduce this profusion to the smallest possible residue of useful and sober facts; to sort out the different names which really belong to the same thing, the different things which have the same name, the things which probably do exist from the things which probably do not, and to present what is known about the probable ways in which the things which remain react together to produce a clot," and it takes some 400 pages to present this residuum. Nevertheless we have nowhere seen it better or more clearly done. The book is divided into two parts: the first deals with the physiology of blood-clotting and some allied problems, the second with the disorders of blood coagulation. Both sections are divided into chapters at the end of which are most useful outline summaries. The first of three valuable appendices presents a scheme for differential diagnosis of coagulation defects, the starting-point being the determination of the "thromboplastin time" (old style prothrombin-time); the second gives properly detailed information about the preparation of reagents, and the third full descriptions of the techniques employed.

This book presents all schools fairly, glosses over no gaps, and gives the most readable and balanced account of the subject available today.

Les vomissements du nourrisson

EMILIO ROVIRALTA, head of the service of pædiatric surgery, Barcelona. Paris: Flammarion. 1952. Pp. 236. Fr. 1800.

THIS monograph does not, as its title might suggest, deal comprehensively with all the causes of vomiting in infancy, but only with those likely to be encountered by the pædiatric surgeon. The author places much value on radiography in the differential diagnosis of the various conditions, and the book is well illustrated with representative radiographs. Pyloric stenosis naturally receives a good deal of space, and the author has observed a striking coincidence of pyloric stenosis with partial intrathoracic stomach, to which he gives the name "syndrome phréno-pylorique." He favours medical treatment for hiatus herniæ, with œsophageal dilatation if stenosis is severe. Among other conditions described are volvulus of the stomach, œsophageal atresia, malrotations, and other congenital malformations of the gastro-intestinal tract. Most of the book is devoted to diagnosis, and it will be useful to physicians as well as surgeons who have to deal with babies.

National Health Service

A Guide for Practitioners. Editor: MAX SORSBY, L.M.S.S.A., vice-chairman, Local Medical Committee, London. Edinburgh: E. & S. Livingstone. 1953. Pp. 262. 12*s.* 6*d.*

EVEN after five years, many doctors in the N.H.S. have only a hazy idea of the administrative side, regarding it as a necessary evil, to be placated rather than understood. This book leaves little excuse for such an attitude. Those creatures of myth, the statutory bodies, here come to life and are seen to be composed of a great many public-spirited men and women, both inside and outside the profession, who devote much time and trouble to the thankless task of administering the service. Not all will agree, however, with Dr. Sorsby's somewhat gloomy picture of the decline of the status of the general practitioner, and he might have added a reminder that general practice is still very largely what the practitioner makes it. An account of the General Medical Services Committee and the British Medical Association is followed by a section on the Special Services, which, as Sir Allen Daley notes in his foreword, reminds doctors of how services needed by their patients, but which they cannot provide themselves, can be obtained. Dr. Sorsby lists some remediable deficiencies and argues forcibly for relieving the general practitioner from the responsibility for getting acute cases into hospital. Such an extensive organisation as ours should surely be able to shoulder this important part of the service, leaving the family doctor freer to do his proper work.

Dr. Horace Joules, looking forward, suggests decentralisation, with integration of all health and social welfare organisations in all-purpose local health authorities, each handling a population of about a quarter of a million. Students, he says, should be taught along lines which will fit them more closely for their future work. He believes that a salaried service will develop, and argues that a list of 3500 will preclude most doctors from giving more than the minimum diagnostic and therapeutic services. Both these points are debatable.

Human Parasites and Parasitic Diseases

K. D. CHATTERJEE, M.D. Calcutta, visiting physician R. G. Kar Medical College, Belgachia, Calcutta. 1952. Obtainable from Das Gupta and Co., 54, College Street, Calcutta, 12. Pp. 766. £6.

THE human parasites of the title are the protozoa and worms which are responsible for disease in man, and a few, like *Endolimax nana*, which are not, but which are important for differential diagnosis. The author describes their structure and biology fully, and the clinical features of the diseases they cause, including treatment, in some detail. He does not seriously discuss prevention and control, except drug prophylaxis, and the sections on transmission by arthropods are not always as comprehensive as one would wish.

Two other features are obvious to the reader. One is that the author's first love is for the protozoa, which are treated and discussed more fully and effectively than the worms; they get 469 pages and the worms 284. The other is that parasites not found in India are not so well done as those which the author obviously knows at first hand. The accounts of the trypanosomes, the schistosomes, and *Onchocerca volvulus*, for instance, fall far short of the excellent studies on the amœbæ, leishmaniæ, and malaria parasites. With these reservations, however, the book is very good. It is not the terse, dogmatic textbook so appealing to the undergraduate, but rather the comprehensive treatise, the reference book, in which one may find accounts of the theories and movements of research, and descriptions of experiments. The long lists of references enhance the value of this book to research-workers. The writing is lucid and the subjects are set out and discussed in a clear and orderly manner. The illustrations vary; the photographs are in general excellent, but some of the coloured drawings (for instance that of *Glossina palpalis*) are less successful. The production and printing are superb.

This is a major work which parasitologists will need and should have. For the next edition Dr. Chatterjee might with advantage ask the collaboration of authors who have met the non-Indian conditions at first hand.

Society and the Homosexual

GORDON WESTWOOD. London: *Gollancz.* 1952. Pp. 191. 9*s.* 6*d.*

THE general tenor of this book is reminiscent of Havelock Ellis: cool, descriptive, unprofessional, socially responsible. The author is well read in the clinical and legal literature of the subject, and has had advice and guidance from Dr. Edward Glover. He makes a sustained plea for more sympathy from the public and more leniency from the law. Most impartial readers will agree with the author that, as things are, a prison sentence is much more likely to do harm than good to homosexual men.

Materia Medica, Pharmacology and Therapeutics (29th ed. London: J. & A. Churchill. 1952. Pp. 512. 20*s.*).—Dr. A. H. Douthwaite took over this popular veteran from the original author, Sir William Hale-White, in 1931; and he has again smartened up his charge. For example, news of the antibiotics, anti-histamines, A.C.T.H., cortisone, and the methonium compounds has been deftly introduced as part of the revision. Some (they will not be students) may mourn the almost complete elimination of pharmacognosy; for the emphasis is now on pharmacology and therapeutics, with a nice tribute to Sir William and a less bustling age in the retention of *Materia Medica* in the title. The regularity with which a new edition has been called for through the years demonstrates the trust of generations.

Fig 3—A consulting room

That on the left reveals the inside of the square with two transplanted silver birches taking root and grass seeds tentatively sprouting The only furniture in the hall is a couple of cheerfully (and differently) coloured metal garden chairs

General practitioners' Wing

The corridor lined by doors leading into the general practitioners' suites is, like the others, notably silent This is due partly to the flooring of rubber squares, and partly to the substance of the walls and ceiling, and in the doctors' rooms double walls make the silence doubly silent On the right of the entrance to each suite is a capacious waiting-room (14 ft square), in front is an examination room (8 ft by 12 ft), and to the left is the consulting room (14 ft square, without fittings)

The waiting room has a large central table and, at present, 20 chairs—though it could take twice this number These chairs, of which the building contains 230, are comfortable, light, convenient, and, as chairs now go, cheaply come by They are made of unpainted 5 ply wood with a laminated back support which gives spring, they are readily stacked, and they cost £2 9s 6*d* each

The examination-room contains a couch and a wash-hand basin and board The consulting-room (fig 3) has a large desk and a wash hand basin and board

Each of these rooms, it may be noted, is differently floored, decorated, and furnished The doctor's room has a parquet floor of split hardwood, partly concealed by a thick carpet, and, in keeping with the present vogue the decoration of one wall differs impressively from that of the three others In this room, too, white-painted venetian blinds of malleable aluminium take the place of curtains

'Combined-services" Wing

Continuing anti clockwise round the square, the next wing is taken up by "combined services" This wing contains a sterilising room, to serve the whole centre, flanked by two dressing rooms It also includes a laboratory, at present used only as a side room, accommodation (but not at present equipment) for an X ray department, and a room (still unoccupied) for a chiropodist There is, too, an excellent gymnasium, with changing rooms attached, intended for use mainly by children with slight physical defects, and another room that will be equipped by the physiotherapist, who has lately been appointed

Child-welfare and School health Clinics

The third side of the square—opposite that occupied by the general practitioners—is devoted to child welfare and school-health service clinics Here the absence at present of an antenatal clinic may seem strange, but in Edinburgh such clinics are usually operated by the hospital service This wing, though connected with the others, can be approached by a separate entrance with, nearby, a covered perambulator park

Near this entrance is a bright children's playroom, with a scaled down lavatory and wash-room attached The floor is tiled with rubber in three colours—blue, yellow, and red—in check formation Most of one side is occupied by a large window, beyond which is a wired in verandah Of the other sides, two are cheerfully painted (one in grey, the other in scarlet), while the large wall facing the window is covered with flower patterned paper—a surprising, and perhaps well judged, deviation from the *Hey-Diddle Diddle* theme that might have been thought inevitable The ceiling is yellow

Another feature of this wing is a kitchen, which can be used for demonstration or for nourishment

The Fourth Quarter

To look at, the administrative wing, which leads back to the main entrance is as fascinating as any other administrative department But it does contain a lecture room and two studies, which are likely to prove useful in connection with the centre's welfare activities and also any teaching of medical undergraduates or postgraduates

Up the Stairs

The four dental surgeries, on the first floor above the administrative wing, have been constructed after much study, including a "mock up" of one surgery Facing north, each surgery has a bay which is wholly filled by a sloping window Two of the surgeries are given over to priority work under the local authority, one is for general dental services, and the fourth is destined for major operations The dentists have their own X ray room and a sitting room

The rest of this floor is taken up by two staff rooms (one for the medical staff) with a kitchen attached

DISCUSSION

This centre, like the few that have already been opened in Britain, is surrounded by question marks The building is not palatial—though the architects delude the visitor into thinking that it is—but it is large and has cost a lot of money, and no one would pretend that we are likely to see many like it taking shape up and down the country

Instead of centres having such a noble start, should they have the sort of start that can be followed up? But then again, how soon can a start of any sort be developed? The construction of health centres calls not only for much money but also for the cooperation of several interested parties, and some such parties are notably uninterested And what of the consumer's reaction? Can we plan for the future on the basis of a few exceptional efforts? May not these efforts recoil on the heads of their planners by attracting patients from far as well as near, thus disturbing a city's health services and dismaying workers in neighbouring areas who are doing their best with less elaborate resources?

What of laboratories and X ray departments? Are they wanted, are they to be run by technicians, and, if so, the urine, but, as a group, those with the ulcer beyond the lesser curvature and those with a duodenal ulcer excreted significantly increased amounts.

Of men with an antroduodenal ulcer all those with a history less than five years excreted a normal amount of urinary pepsinogen, whereas those with a history longer than five years excreted an amount which increased progressively with the length of history, up to about three times the normal figures.

The test is of little value in routine gastroduodenal diagnosis.

My grateful thanks are due to Dr. F. Avery Jones, who suggested this investigation and has been a source of advice and encouragement throughout. I should also like to thank Dr. G. Discombe for laboratory facilities and advice on technical matters, and Dr. R. Doll and Mr. A. Heady for suggesting the statistical methods used and for their critical reading of drafts.

MUMPS ORCHITIS WITHOUT PAROTITIS IN INFANTS

NEVILLE K. CONNOLLY
M.D. Harvard, F.R.C.S.
SENIOR SURGICAL REGISTRAR, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

THE commonest cause of an acute swelling in an infant's scrotum is an indirect inguinal hernia, which may be very difficult to reduce. From these herniæ can be separated the cases where it is possible to "get above the swelling," and these fall into two groups: those due to torsion of the testicle or of the testicular appendix; and those of unknown cause. In these there is swelling of the testicle itself, with or without involvement of the epididymis, and with œdema of the scrotal skin. I report here one such case which was shown by serological tests to be almost certainly mumps orchitis, and suggests that this virus may be responsible in many other similar cases.

Although Hippocrates knew of an epidemic swelling near the ears sometimes associated with orchitis, and Hamilton (1790) gave the classical description of mumps, it is not until quite recently that we have understood that this is a generalised infection. It was known that orchitis occurred without parotitis in young adults during epidemics of mumps, and it was suspected that meningo-encephalitis might have a similar ætiology. Kane and Enders (1945), using serological tests, showed that the central nervous system was involved in mumps even when there was no parotitis. Henle et al. (1948) have shown that man can develop antibody to the mumps virus and excrete the virus from the salivary glands without any clinical evidence of mumps. Before this it was considered that mumps was an epidemic disease of the salivary glands that occasionally affected the gonads also.

The present conception is that mumps is due to a specific virus, which may be neurotropic (Philibert 1932) and circulates in the blood after multiplication, presumably in the salivary glands. During the viræmic phase the virus may become localised in several of the glands, of which the testicle is the commonest.

If infection of the central nervous system is always present it gives symptoms in only about 10% of cases, although a higher percentage show a cellular reaction in the cerebrospinal fluid (Candel 1944). However, the signs of meningitis may be the only indication of the disease, and the diagnosis can only be made with certainty by demonstrating rising antibody titres. The same is true for orchitis. After puberty orchitis is known to be common with mumps, varying from 16 to 64% with different epidemics at least half of the cases being only slight. Only one case of mumps orchitis in infancy has been published (Steiner 1896), and the diagnosis was based on circumstantial evidence, the infant having no parotitis. No reports have been published of any attempts to show by serological evidence that any infants have had an orchitis caused by the mumps virus.

Henle et al. (1947) have shown that, in mumps, two antibodies develop—a soluble antibody (S) and a virus antibody (V). The S titre rises quickly and starts to fall after three or four weeks, whereas the V titre rises and falls more slowly and remains high for a longer time. Traces may persist for months, if not longer. If complement-fixation tests are done on the patient's serum, it is possible, by tracing the rising and falling titres, to prove the identity of the infecting agent. With single tests a high S titre is good evidence of a recent infection. In infants there might possibly be both S and V antibody in various amounts due to passive transfer across the placenta; but this is only likely where the mother has had a recent attack of mumps. On this basis it should be possible to diagnose both meningo-encephalitis and orchitis in infancy if they are due to the mumps virus. Perhaps this virus causes symptoms in the central nervous system and the testis more readily than in the salivary glands in infants.

CASE-RECORDS

Case 1.—A boy, aged 7 months, was brought to the casualty department of this hospital on April 15, 1952, with a swelling of the right side of his scrotum. His mother said she thought he had been unwell for about a week, because he had had disturbed sleep and "kept lifting his bottom as though it hurts." She also thought that he had been feverish, and her doctor had confirmed this two nights ago. However, the infant had not vomited, fed well, and had normal micturition and bowel actions. On the morning before he was brought to hospital he developed a swelling of the right side of the scrotum, which became red.

On examination he was well nourished and rather flushed (rectal temperature 102·6°F), with a swollen reddened right side of the scrotum, which felt œdematous. The right testicle could be distinguished from the epididymis and was three or four times the normal size; it seemed tender and was firm to palpation. The cord was thickened, soft, and boggy, but contained no nodules. There was some enlargement of the inguinal glands, more marked on the right than the left. There was no enlargement of the salivary glands and no change in Stensen's duct.

Treatment and progress.—Mumps orchitis was suspected, even though the mother denied any contact or that there was any mumps in the neighbourhood. Sulphadimidine was prescribed as a precautionary measure, and the infant was given chloral and sent home. Two days later, when he was seen again in the outpatients department, the orchitis was subsiding. Two weeks later the orchitis had completely settled, but his mother volunteered that his older brother had developed parotitis, which had been diagnosed as mumps on April 20—i.e., five days after the patient had developed his scrotal swelling. Further, she had discovered that several of the neighbouring children also had mumps.

Complement-fixation tests.—To adduce further evidence for the diagnosis of mumps, this infant and his brother were referred to Dr. J. A. Dudgeon, who tested the sera for mumps antibodies. Blood was taken from both boys on May 13, about four weeks after the onset, and complement-fixation tests were made according to the method of Henle et al (1947) The following titres were found

	Mumps V	*Mumps S*
Patient	1 80	1 40
Brother	1 160	1 80
Control (negative)	Nil at 1 10	

These findings strongly suggest that both the patient and his brother were infected with the mumps virus about *four weeks before the blood was taken* At this time the infant had orchitis without parotitis

Case 2 —A boy, aged 6 months, was admitted to the Jenny Lind Hospital, Norwich, on April 11, 1951, with a tender swelling of the left side of his scrotum The swelling had developed during the twenty four hours before admission, and there appeared to be little systemic disturbance There was no vomiting, and the infant fed well

On examination he was well nourished, weighed 21 lb (birth weight 8 lb 7 oz), and had slight pyrexia (temperature 99 8°F), a clean tongue, no enlargement of the salivary glands, and no redness of Stensen's duct The left side of his scrotum was swollen, with the skin thickened and reddened The left testicle and epididymis were enlarged to about three times the normal size but could not be clearly distinguished from each other The cord was swollen but soft and contained no nodules It was possible to get above the swelling but there were palpable inguinal glands, chiefly on the left side It was decided to explore the scrotal contents to exclude a torsion of the testicle

At operation the same evening the scrotum was incised and the thickening of the skin appeared to be due to œdema The tunica vaginalis was thickened and, on being opened, let a little clear fluid escape, revealing a swollen firm testicle two or three times the normal size and bluish white except for a few punctate hæmorrhages The testicle was anterior to the epididymis, and the mesorchium was very short The cord was thickened with œdema but not twisted The tunica albuginea was not split The scrotal incision was closed, with a small rubber drain down to the tunica

Postoperatively the boy's temperature was 101 8°F next morning but fell to normal in the next twenty four hours The swelling rapidly subsided, and the infant was discharged seven days later

Follow up —Three weeks after discharge the infant was again examined and the testicle felt quite normal, but just *over a year later it was only half the size of the one on the right* side

DISCUSSION

When case 2 was treated, I suggested the diagnosis of mumps orchitis, but this was considered untenable because mumps orchitis was reputed not to occur in infancy and to be extremely rare before puberty In the light of the subsequent case 1, and because the findings at operation were so like those described by Smith (1912), Gall (1947), and Charny and Meranze (1948) in adult cases of mumps orchitis, I maintain that my suggestion was correct, and that this infant did have mumps orchitis

In the last four years, since the beginning of 1948, seven infants aged less than 1 year have been seen at Great Ormond Street with acute painful swelling in the scrotum, excluding cases of hernia Three of these proved to be cases of torsion, but the remaining four, including case 1, were diagnosed as non specific epididymo orchitis or partial torsion One of them was operated on, and the findings were very like those in case 2 Possibly all four of these cases were really mumps orchitis, if this is so, *mumps orchitis is commoner than torsion in this small series*

Treatment

The treatment of mumps orchitis remains controversial but in the more severe cases in adults drainage of the hydrocele by opening the tunica vaginalis relieves the symptoms and brings the temperature down by crisis (Nixon and Lewis 1946) Wesselhoeft and Vose (1942) maintain that it is necessary to incise the tunica albuginea as well to prevent the pressure atrophy of the contents However, the pathological studies of Charny and Meranze (1948) refute the usefulness of this procedure, they state that the material which they examined indicates that the testicular damage is not due to pressure atrophy and the testicular œdema is not severe They maintain that the seminiferous tubules are invaded in a patchy, but not usually complete, way with inflammatory cells, and the tubules so affected atrophy while the others survive This is not a complete confirmation of the findings of Gall (1947) or of the report of Wolbach cited by Smith (1912) Both these workers, while agreeing about the infiltration with inflammatory cells, consider that there is also a good deal of œdematous reaction within the testicle Several of the operation notes of reported cases of mumps orchitis mention the fact that, when the tunica albuginea is incised, the contents do not tend to be extruded Further study of this question seems to be required, because the advocates of opening the tunica albuginea maintain that testicular atrophy can be prevented if this is done soon enough, and the clinical benefit of merely opening the tunica vaginalis is well substantiated The problem is not easy to resolve, because testicular atrophy by no means always follows mumps orchitis, and, when there is some atrophy, spermatogenesis is usually diminished rather than abolished Sterility is rare, even after untreated bilateral orchitis, and the endocrine function of the testes seems to be unaffected The impotence which has been reported is almost certainly psychological

If my contention that the mumps virus is a common cause of orchitis in infancy is proved to be correct, and more cases are diagnosed as such, this diagnosis should only be made with the utmost caution Though it is relatively simple to differentiate between this condition and a hernia, even when the latter is irreducible and causing acute symptoms, it is not at all easy to differentiate between mumps orchitis and torsion In case 1 torsion was excluded because of the history of a week's lassitude, the pyrexia, and the palpation of a swollen testicle separate from the epididymis and mobile in the scrotum None of these points of differentiation was present in case 2 *If there is any doubt, the scrotal* contents should be explored at once, and, if the findings suggest orchitis, no further treatment is necessary, unless it be to incise the tunica albuginea, when a biopsy specimen could be taken If there is torsion, this can be dealt with Serological tests can be undertaken afterwards in the orchitis cases to establish the ætiology, but operation should not be postponed while their results are awaited

SUMMARY

The present concept of mumps and the usefulness of serological tests in diagnosis are discussed

A case of mumps orchitis without parotitis in an infant, where the diagnosis was supported by a complement fixation test, is reported, and a further similar case, which was operated on but in which no serological tests were made, is added

It is suggested that orchitis in infancy may often be due to mumps

All doubtful acute scrotal swellings should be explored by operation

I wish to thank the surgical staff of the Hospital for Sick Children, Great Ormond Street, *for permission to use their* records, Mr A B Birt, F R C S, for permission to publish case 2, and Mr *Denis* Browne, F R C S, *for much* helpful advice

who is to supervise the work ? Indeed, is it economic to have an X-ray department for, say, 20,000 people ?

These questions are not new: what is new is the occasion, by practice, to grope towards some of the answers. Most of the questions concern the general practitioner; and unfortunately to some of them no final answer is possible until the rôle—and the will—of the practitioner in this new age is seen more clearly. This, of course, is no reason for not pressing on with health centres; for these may themselves help to determine the practitioner's rôle and will. The immediate need is for experience with centres large and small, elaborately and simply equipped; and it is to be hoped that the opportunity at Sighthill will be fully seized by equipping the X-ray department, and by trying different forms of operation and control both here and in the laboratory.

As to economy, at Sighthill the playroom, the gymnasium, and one or more of the staff rooms are perhaps dispensable. Elsewhere in the building—and especially in the general-practitioners' suites—advantage will no doubt be taken of the flexible design to experiment with smaller rooms, in order to establish the sizes that are most economical of space without being inconvenient or oppressive. Perhaps, too, experience may show that practitioners and patients will accept less rigidly secluded waiting-rooms.

With regard to construction materials, the copper roof is a little flourish that will not always be repeatable; and similarly hardwood may be less prominent in later centres. But, all in all, the designers have made good use of ordinary materials, abjuring the exotic.

Meanwhile, plans are well advanced for the second Scottish centre, which is to be built at Stranraer, near the hospital. It is to be rather smaller than that at Sighthill; but this will not stop the Health Department's architects from feeling sedately elated at the prospect of once more escaping from the fantasy of the drawing-board into the actuality of bricks and mortar—and colour.

SENIOR REGISTRARS

THE Minister of Health and the Joint Committee for Consultants and Specialists have been discussing the position of those senior registrars in England and Wales whose appointments will soon be ending in accordance with the arrangements made in 1951 for reducing the number of senior-registrar posts to bring it more into line with the estimated number of vacancies for consultants and senior hospital medical officers in the various specialties. The Joint Committee have represented to the Minister that to avoid undue hardship a longer time should be allowed for this adjustment to be brought about, so that in suitable cases these senior registrars and former senior registrars may have longer to seek higher hospital appointments or other medical posts outside the hospital service. The Minister has come to the conclusion that transition to the senior-registrar complement envisaged by the plan of 1951 may be smoothed in that way without detriment to the hospital service.

Accordingly the Minister has authorised hospital boards to retain senior-registrar posts in excess of those covered by the plan of 1951, for a period not extending beyond the end of 1955 at the latest, where this will avoid extra staff having to be employed in other grades and, fully suitable candidates are forthcoming for the retained posts.

As the engagements of the present holders come to an end the posts which are to be retained will be advertised. Applications will be entertained from the present holders, from other senior registrars whose appointments will end in the near future, and, in certain circumstances, from former senior registrars. The term of these posts will be one year, but boards will be free to allow a second year where other employment has not been obtained by the end of the first year.

Though the holders of these posts will continue to be free to compete for higher hospital appointments, they will do so in competition with other candidates, and their retention as senior registrars will not give them any special claim or constitute any guarantee that they will be successful in the competition.

In addition, there will still, of course, be nothing to prevent a retiring senior registrar from applying for, and being appointed to, a post within the training establishment. If, however, he is reappointed to the same post, the term of his reappointment will be limited to two years.

The Joint Committee have expressed their agreement with these arrangements.

MINISTRY'S OBSERVATIONS

The Ministry of Health, in a letter to hospital boards, states:

"Where it is decided to retain a post it should be advertised at the appropriate time as a post for one year, with a possible extension to two years (but not beyond 31st December, 1955) if the holder has not obtained other employment in the meantime. The present holder will be free to compete for it and applications should also be entertained from any other persons in their fourth or subsequent years as senior registrars in the specialty and those who though not now holding posts as senior registrars have occupied such posts for three or more years and have vacated them since memorandum RHB(50)106/BG(50)96 was issued on 6th November, 1950. The applications should go to the Appointments Committee for consideration and recommendations. It is most important that there should be a genuine competition which gives equal opportunity to the present holder of the post and to others similarly situated.

"Where a transitional post becomes vacant before 1st January, 1955, it may be advertised again but transitional posts becoming vacant on or after that date should be abolished and other arrangements made for the work hitherto performed by the holders.

"In some regions where the reduced establishment of senior registrars has already been reached, it may be that in the case of a few of the posts which have been abolished difficulties have been caused in the staffing of the hospitals and to the men in posts similar to those which this scheme is designed to relieve. In such circumstances the Minister would see no objection to the revival of a post temporarily as a transitional post, but this should be exceptional. . . .

"In their own interests it should be made clear to successful applicants that their selection for transitional posts must not be taken as conferring on them any special claim to higher hospital posts or constituting any guarantee of their being successful in due course in the competition for these posts. . . .

"It is essential that this transitional arrangement whould not interfere with the four years training plan and that the number of posts within this plan should not be reduced on account of the retention of the transitional posts. The Minister regards it as of the greatest importance that the opportunities of younger men who wish to start training in the senior registrar grade should not be prejudiced by the new arrangements.

"There can, of course, be no objection to a senior registrar who has completed training in one specialty transferring to another specialty and completing a further four years in this second post; such interchange may be of great benefit to the specialty. There is also nothing to prevent a fourth year senior registrar from applying for the same or another post in the same specialty which falls within the training plan, but it is essential that his greater experience should not determine his appointment rather than that of a potentially better future consultant and in any case no senior registrar should be reappointed to the same post for more than an additional two years. The criterion for selection should always be that the applicant likely to make the best consultant at the end of his four years training should be chosen."

One or two schemes had been set going whereby patients could be discharged from hospital properly and rather more quickly than before At Cambridge, with the coöperation of general practitioners and the district nursing service, some surgical patients with clean operations were discharged from hospital within four or five days He agreed with Lord Moran that the teaching of nurses should be done at the bedside We seemed at present in danger of getting too many nurses trained to too high a standard They were in fact going to be not very good doctors rather than very good nurses The nurse so trained looked for an administrative job, no other would give an increased salary

Lord Haden-Guest regarded dilution of the nursing profession as a defeatist policy We must do something which was more productive of efficiency It was true that there was a great deal of difference between ordinary nursing and nursing in a mental hospital, but the use of the word "dilution" was unfortunate, because there was already too much dilution in the nursing profession It was better to have carefully trained people rather than those who had just picked up knowledge as they went along He saw no immediate solution in prospect, and the Nuffield report did not in fact offer one What it offered was a survey of the facts, and he would like to know what action the Government were prepared to take to remedy the situation revealed in the report

Lord Woolton, Chancellor of the Duchy of Lancaster, replying for the Government, said that the discussion might lead one to think that the situation was worse than it actually was The nursing force in this country had increased by two and a half times in the last 50 years The demand had increased even more, but that also was a sign of progress, more care was being taken of the sick Nursing staff was recruited not so much by stereotyped regulations as by showing people who might enter the nursing profession that it was held in high esteem The Nuffield report offered a wealth of new information, and the Minister of Health had at once summoned his advisory committee to consider what action should be taken Lord Woolton was not so depressed as some of the speakers by the fact that 74% of the basic work in hospitals was done by student nurses A great deal of that work did not require high professional skill, but it did require a great deal of personal kindness In talks with nurses he had been horrified to find that promotion went in the line of administration It was a great pity if highly trained nurses were being called upon to do clerical work which involved an entirely different sort of capacity and different attitude of mind It seemed to him from this report that they ought to see what reorganisation could be obtained both in the direction of the personnel employed in administration and also in the fuller use of orderlies

In the last four years the number of full-time trained nurses in England and Wales had gone up from 40,000 to 47,000 and student nurses had gone up from 42,000 to 50,500, there had been a drop from 12 000 to 11,500 in assistant nurses, and other nursing staff had risen from 16,000 to 25,500 making a total of 135,000 full-time nurses compared with 110 000 in 1948 In 1948 the shortage of beds due to the shortage of nurses was 57 000 Last year the figure was 28,500 When the Minister of Health urged the hospital authorities to cut staff he stipulated that this must not be done by throwing domestic work on to the nurses The reason for the restriction of the engagement of nurses was that the Minister felt that the problem was becoming to a considerable extent one of distribution of nurses Some places were considerably better off than others, though still short and in order that the nurses might be employed to the best advantage the Minister brought in the restriction order

Therapeutic Substances (Prevention of Misuse) Bill

Mr Iain Macleod the Minister of Health, in moving the second reading of this two-clause Bill[1] in the House of Commons on May 13, explained that the Penicillin Act, 1947, had been found to be too narrow because it applied only to antibiotics Clause 1 of the Bill was, he admitted, extremely wide, and on principle he did not like to ask for such wide powers But he thought it right to do so because we were in an age of immense advances in chemotherapy and we did not know what sort of substances would be discovered He was therefore asking for powers to make regulations similar to those made under the 1947 Act in respect of any substance which appeared to the Minister of Health capable of causing danger to the health of the community

Isoniazid, the drug which had given rise to this clause, was a simple chemical substance it was cheap to make and it could be bought over a chemist's counter At the moment the Pharmaceutical Society had suggested to their members that it should only be supplied on a doctor's prescription But Mr Macleod felt that this arrangement did not discharge his duty to the public and that it was more satisfactory that he should be enabled to make regulations for isoniazid similar to those that could be made for antibiotics

According to the Bill, before making a regulation he would have to consult the Medical Research Council and he was prepared to give an assurance that he would also consult the manufacturers concerned This was the general practice under the Penicillin Act and he would be prepared to continue these consultations provided it was clearly understood that the final decision must be taken only on medical grounds

The second clause, popularly known as the penicillin for pigs clause was, Mr Macleod admitted, to use the Prime Minister's accidental coinage, a pigmeal solution to a new problem It had been found that the addition of a minute quantity of antibiotics to feeding stuffs had a remarkable effect in encouraging the growth and fattening of pigs The Medical Research Council had assured him that this addition would have no adverse effect upon human beings who ate the meat thus produced He would guard against the possibility of creating by this wider use of antibiotics a sort of black market in penicillin by ensuring that the antibiotics were used in such a way that they could not be extracted and used for medication At the moment he would only make regulations applying to penicillin, because this was the only substance of this kind of which we had sufficient supplies But it was possible that later aureomycin and terramycin would also be used for this purpose

Mr Macleod admitted that he had several times boasted that he had not introduced any legislation, in extenuation he pleaded that this was only a little Bill, which wisely extended an Act which had been found to be too narrow and which brought forward a new and most interesting use for antibiotics which might have a most important effect on our food-supplies

QUESTION TIME

Hospital Nursing Staffs

Mr R W Sorensen asked the Minister if the distribution of nursing staff among hospitals had improved as a result of the reviews of hospital staffs made at his request by hospital authorities —Mr Iain Macleod replied It is too early to assess the results of the reviews of hospital staffs, but I hope that they will make a useful contribution to the improvement in the distribution of nursing staff which I am seeking to achieve by this and other means

Mr Sorensen In the meantime is anything being done to secure a more equitable distribution of the nurses available since some of the hospitals are virtually understaffed and others grossly overstaffed ?—Mr Macleod That was one of the thoughts in my mind when I issued the circular which has received so much criticism, but other progress is going on all the time The line that seems most promising at the moment is the seconding of nurses, which is being done increasingly over the country, particularly to sanatoria

Mr A Blenkinsop Will the Minister at the same time make sure that there is no suggestion of compulsory secondment, in view of the attitude which I am sure the nursing associations would take on the matter ?

Hospital Circulars and Regulations

Mr S Hastings asked the Minister if he would issue a booklet with index giving a summary of the regulations issued by his department to hospitals since the appointed day which were still in operation —Mr Macleod replied I assume the hon

In England Now

A Running Commentary by Peripatetic Correspondents

It is of course impossible to get inside the mind of a tubercle bacillus, to appreciate its hopes, joys, conflicts, and despairs ; but we can safely assume that, in common with all other living creatures, it is deeply conscious (*a*) of having a value, and (*b*) of being incomplete. Otherwise why should it go on going on as it does ?

Its behaviour is certainly changing. Either it has learned by experience (which, experience teaches us, is extremely unlikely), or else its world-environment, to which it has to adjust, has been altering in character. Not so many human generations ago (but millions of T.B. generations ago) it used to make its home in young human beings, where its standards of living were so prodigal that it ran through the available resources in a matter of months, bankrupting its host who then, as you might say, died of galloping consumption. Thus large families of bacilli would perish miserably and be buried in a common grave—all except the few who, going while the going was good, achieved extremely hazardous airborne emigration to virgin territories. They were hectic times. It was a short life, but, we can only hope, a gay one.

Airborne emigration (or deportation) still helps to solve problems of overpopulation and famine, but nowadays the immigrant seems to behave more circumspectly. Many are content to join the closed community of a primary focus. Kept on short commons, in cramped quarters, they live under a monastic discipline ; but they survive. Some fine old families must have been eking out an existence on the same small holding for more than half a century. There can be no promiscuous population-increase and no overcrowding. The B.C.G. in particular seems innately schooled to respect its billets and does not go " chopping down doors and staircases for firewood," and longevity is its reward for this consideration.

But " for aye to be in shady cloister mew'd " is not every bacillus's cup of broth. Given half a chance, bolder spirits will break loose and abuse hospitality. There is this difference, however : their host has met their sort before and has become (to coin a phrase) somewhat allergic towards them. The would-be marauders are hampered at every turn by Defence of the Realm Regulations. Life is altogether much harder for them. All legislation, they will learn, is devised to prolong life, not to make it easier or more enjoyable.

The introduction of antibiotics is doing much to ensure the survival of the few : those privileged classes who are snugly ensconced in their family seats. Vagrants, even if they do not perish, are rendered impotent to found dynasties and eventually must die of old age without issue. And now there is a worse threat which the race will have to meet. A.C.T.H. would appear to burn down the fortresses and turn the inhabitants loose, in the byways, where they fall an easy prey to the antibiotics. But, as their leader might remark " We have faced fearsome odds in the past and have survived. The magnitude of the threat will not dismay us. We will hold our ground and show our true colours in every clime—even where baths of acid may blanch the weaklings. Our ancient cultures must not be allowed to perish."

* * *

The missionaries of the 19th century are often criticised for having insisted that their naked converts in tropical countries must be clothed. The missionaries are accused not only of having disrupted local customs, but also of introducing unhygienic habits among those who are unable to wash their garments as often as is desirable in a hot climate, of having thus encouraged body parasites and the diseases they carry, and of having spread malnutrition by preventing the synthesis of vitamin D from the action of the sun on the uncovered skin. Nowadays missionaries are better informed, and few of them think that, unless an African or a Polynesian is forced against his or her will into some garment at least as unrevealing as an Edwardian bathing dress, salvation is impossible.

But times have changed, as debates in the Nigerian house of representatives in Lagos show. Several Nigerian politicians have urged that legislation should be introduced to make nudity illegal. They argue partly on the grounds of decency and modesty ; but it is clear that the main reason for their proposal is political. In countries which are striving for self-government, the word " primitive " is considered insulting, and people who go around without clothes are looked upon as primitive. To make things worse, visiting journalists and anthropologists even take photographs of these naked villagers, and when these appear in magazines abroad it is alleged that they damage the prestige of the whole Nigerian people. In the debates it was left to government officials to point out that to insist that, for instance, the pagan tribes on the plateau in Nigeria wear clothes is to ignore the customs and traditions of the people, for in some areas wearing clothes is still considered a sign of loose living. These European officials then found themselves attacked for attempting to keep the country in a state of servitude.

* * *

It sometimes seems to me that what is really holding up the great chlorophyll controversy is our lack of a unit of scent ; and here I believe I can help. After some thought, I have rejected the olf and the pong, and I now finally come out in favour of the smel. One smel shall be the effect produced at standard temperature and pressure, and at one metre distance from the nose, of—what ? A red, red rose ? A piece of musk ? One milligramme of methyl mercaptan ? Perhaps a kipper could be kept at the National Physical Laboratory under exactly the right conditions, and we could standardise from there, the technique to be known as the Beezer Test. The most delicate redolence would come in millismels ; a microsmel for a fragrance ; at the other end of the scale we would have the kilosmels and macrosmels produced by farmyards, glue factories, and sulphuric-acid works.

* * *

How fitting that the giant slab of glass and concrete which houses the U.N. secretariat should dominate the East River. New York is the gateway through which successive waves of immigration have flowed into America, each leaving a backwater in the city. Italians, Germans, and Jews have their own colonies, and Chinatown is a fantastic little oriental pond among the skyscrapers. Now the floodtide of Puerto Rican immigrants pours into the East Side unchecked by McCarran since they are American citizens ; there they are packed 8 or 10 to a room and the local cinemas show films in Spanish. My barber is a German who scarcely speaks English, the janitor is Austrian, and the elevator operator Italian. Yiddish newspapers are sold at the nearest street-corner and a babel of foreign tongues and broken English surrounds the Irish traffic cop on Broadway. In this cosmopolitan cauldron of first-generation Americans, the only " foreign " accent is a British one.

Ward rounds are linguistic exercises. There is the South American coronary who speaks a little French, and the Pole who describes his hæmatemesis with gestures and a few words of German ; and today an S.B.E. from East Germany lay under a huge placard bearing the painfully inscribed cri de cœur, " I HURT ALL OVER."

* * *

The dog is a poodle, somewhat careless in his dress and casual in ablutions, but nevertheless of an apparent innocence that attracts everyone. He belongs to my neighbour, but a few days ago was in my garden, as is his custom, and honoured us (in our absence) by entering the house. There he found a box of thyroid tablets within his reach. They were active tablets, made by a well-known firm and of the strength of gr. 1½. This he could not have known, for he at once consumed gr. 147. Today he is in the garden again and I have the honour to record the important clinical observation that thyroid gland has no obvious or statistically significant effect upon voice production in the poodle. But there is a look in his eye which I have not noted before. I suspect some lowering of the innocence threshold.

* * *

Now that judges are prepared to decide for us not only which papers we ought to read but also which to believe, may we look forward to a decision—from the House of Lords of course—in the case of Walshe *v.* Fulton : in *re* the Motor Cortex ?

Member has in mind circulars issued to hospital authorities Some consolidation on particular subjects has already been effected, and this will be extended as circumstances permit A useful index to all circulars is prepared annually by the Birmingham Regional Hospital Board and is widely circulated

Tuberculosis Among Immigrants

Mr **SAMUEL STOREY** asked the Minister what proportion of the notifications of tuberculosis referred to persons who had recently entered the country from Eire —Mr **MACLEOD** replied The present returns from medical officers of health make no distinction as to nationality

Mr **STOREY** In view of the fact that the incidence of tuberculosis is 50% higher in Eire than it is in this country, and also that in some parts of the country a large proportion of infections are amongst persons who have recently come from Eire, does the Minister not think it a good thing to insist upon radiographical screening and a certificate of fitness before allowing people to come from Eire to seek employment in this country ?—Mr **MACLEOD** There are a number of other people and Ministries involved in this The hon member is quite right that a certain amount of difficulty has been caused by people coming from Eire, and I will see whether we ought to get more information on this subject and whether steps should be taken at the ports and airports

Mass Radiography

Dr **BARNETT STROSS** asked the Minister how many mass-radiography units were in use in England and Wales, what was the approximate number of cases X rayed per week or month, and how far the number of units in use was to be increased in the near future —Mr **MACLEOD** replied 63 units are now in use Last December the 62 units then in use made 190,386 examinations 5 additional units have recently been allocated and arrangements are in hand to bring them into operation

Bone-conduction Hearing-aids

Replying to a question, Mr **MACLEOD** stated that up to April 18, 958 patients in England and Wales had been supplied with bone conduction hearing aids

Fibre-glass and Industrial Injury

In answer to a question Sir **WALTER MONCKTON**, the Minister of Labour, stated that the Factory Department had maintained a close watch on the manufacture and handling of fibre glass in factories, but there was no evidence to show that it was injurious to the lungs, although it might give rise to a mild skin irritation which soon disappeared Samples of materials consisting of fibre glass and resins which were now being used in the aeroplane industry were being investigated microscopically by the chemical branch of the Factory Department to determine the size and nature of the dust given off when components made from these materials were machined

Vivisection Licences

Mr **PETER FREEMAN** asked the Home Secretary how many certificates were issued last year to perform experiments on living animals under the Cruelty to Animals Act, 1876, in how many cases no experiments were performed, and whether he would consider curtailing the issue of such unnecessary certificates —Sir **DAVID MAXWELL FYFE** replied In 1952 I granted 678 licences, valid for five years During that year 1335 licensees performed no experiments under the Act Every year the revocation of licences which have not been used during their currency is reviewed

Mr **FREEMAN** Many of these 1335 have never performed a single experiment since they first received a certificate, and will the Minister not consider curtailing the number of certificates issued in this way ?

Sir **DAVID MAXWELL FYFE** We keep a check on current years to find the licensees who have not performed an experiment When we have discovered this we work back to see whether they have up to that time not performed an experiment for, say, four or five years If they have not we prune the list

Use of Agene in Flour

Lord **HANKEY** asked Her Majesty's Government for lists of countries in Europe and North America in which the use of agene in flour for human consumption was permitted and of those countries in which agene was prohibited

Lord **CARRINGTON**, the joint parliamentary secretary to the Ministry of Agriculture and Fisheries, replied The treatment of flour for human consumption with nitrogen trichloride (agene) is permitted in the United Kingdom, Eire, Holland, Germany, Norway, Denmark, Italy, Sweden, and Finland It is prohibited in Canada, the United States, France, Belgium, Spain, Portugal, Switzerland, Turkey, and Greece

Medical Posts in the Civil Service

Dr A D D **BROUGHTON** asked the Secretary to the Treasury in which medical journals he now advertised the vacancies for appointment of registered medical practitioners in the Civil Service —Mr J A **BOYD CARPENTER** replied None, Sir Since no recruitment is taking place, vacancies are not at present being advertised at all

Dr **BROUGHTON** Can the Financial Secretary state in terms which are more easy to understand why there have been no advertisements of civil servant medical officer posts in the medical journals recently ? Is it possible that the Financial Secretary is in disgrace with the medical profession, and that the British Medical Association has imposed a ban upon the publication of advertisements of this sort ? If that is so, would he inform the House what the trouble is about ?

Mr **BOYD CARPENTER** Those issues, particularly the one relating to myself, are of an intriguing character, but they are wholly different from the point raised in the question The hon. gentleman asked in which medical journals vacancies are advertised, and the answer that I have already given him is " None "

Synthetic Detergents Inquiry

Mr **HAROLD MACMILLAN**, Minister of Housing and Local Government, in a written reply said that after consulting the Secretary of State for Scotland and the Minister of Health he had appointed a committee with the following terms of reference

> " to examine and report on the effects of the increasing use of synthetic detergents and to make any recommendations that seem desirable with particular reference to the functioning of the public health services "

The chairman of the committee is Sir Harry Jephcott, F R I C, and the 14 members include the following doctors

Dr N R Beattie, principal medical officer Ministry of Health (attached to Ministry of Housing and Local Government) Dr J C Cruickshank, professor of bacteriology as applied to hygiene London School of Hygiene and Tropical Medicine, Lieut -Colonel E F W Mackenzie director of water examination, Metropolitan Water Board

---

Public Health

Smallpox

No new cases were reported from Yorkshire in the week ended at noon on May 19, but the Baildon miner who was admitted to hospital with smallpox on May [illegible], died on May 13 The total number of confirmed cases in the outbreak is 30, including 8 deaths The last patient who might have spread the disease was taken to hospital on May 5 Although the period of surveillance of known contacts has almost expired special vigilance must be maintained for a longer period because the source of infection of 4 patients who fell ill several weeks ago has not been traced

Diphtheria Immunisation in Antrim

In his report for 1951, Dr P V Pritchard, medical officer of health for county Antrim, says that not enough children are being immunised against diphtheria to maintain a safe level of protection in the county Figures for 1951 indicate that less than 30% of the children are being immunised Dr Pritchard points out that the facilities for immunisation in the county are not as extensive as elsewhere, for the county health committee's instructions are that immunisation should be carried out solely by general practitioners except in a small minority of cases dealt with by medical officers of the public-health department at long established clinics The committee lately reconsidered the matter, but decided to continue the present system and not to extend immunisation in clinics Some Antrim doctors claim that a satisfactory number of children are being immunised and that the figures are unreliable because returns are incomplete But Dr Pritchard says that an inquiry into the quantity of diphtheria prophylactic supplied to doctors in the county has failed to support this claim In his view the only solution is to offer the public the alternatives of immunisation by the family doctor or at a health committee clinic

Letters to the Editor

THE PROBLEM OF PEPTIC ULCERATION

SIR,—Michael Smyth cannot goad me into a quarrel. I have too high a regard for him. His enthusiasm and his "fine careless rapture" are a joy to all who have the privilege of his friendship. I think, however, that he begs the question when he says: "If it were possible to cure a patient's duodenal ulcer, and leave him with the whole stomach, this should be done: better a whole stomach than an austerity remnant with its dumping syndrome and all that."

It is not possible. Gastrojejunostomy leaves, not a whole stomach, but a stomach with a hole—a very different matter. Having secreted a ferment in response to a meal, the stomach now finds when it gets to work that there is no meal left, and nothing to digest but itself. Gastrojejunostomy does not cure ulcer, but merely shifts the seat of attack somewhere else. A review of the records of New Lodge Clinic would give Mr. Smyth the low-down on some of his friends.

With regard to "austerity stomachs," the whole point of my article, if it had any, was to debunk and discourage the "austerity stomach" with its dumping syndrome and all that. A good gastrectomy does not dump. It does not develop another ulcer. Why therefore do a bad one that is likely to go wrong merely because it is easier to undo when it does go wrong?

Let us get rid of this eponymity in gastric surgery. Most of it is wrong anyway. All gastrectomies are modifications of the Billroth I or the Billroth II, and who modified them is anybody's guess. Who was Hofmeister? Who was Polya? Neither Michael Smyth nor I were operating when gastric surgery was being designed, but Richard Lewisohn of New York, the man who introduced blood-transfusion to surgery, was. Lewisohn was first assistant to Czerny, the inventor of the Lembert suture, and knew all the men whose names are now history. He writes[1]:

> "The reader may be surprised to hear that about thirty years before Hofmeister and Polya the principles of both methods were described, the first by von Eselsberg in 1889, the second by Kronlein in 1887."

The so-called Hofmeister technique, as reference to any textbook of the time will show, was merely a transverse gastrectomy with a reduced opening—an unsatisfactory job. The wide application of proximal jejunum to lesser curve was introduced by Lake and Finsterer. Finsterer's plan of attaching transverse colon to stomach has been abandoned in the modern operation because it distorts the proximal jejunum, and because the leak it was designed to forestall does not happen.

London, W.1. HENEAGE OGILVIE.

JUNIOR HOSPITAL STAFF

SIR,—I have been privileged to read the paper by Hurst, Linfoot, and Woodhouse before publication.[2] I think they state the present difficult position very well, but I must disagree with several of their conclusions.

1. I do not think there is an absolute shortage of doctors, only a maldistribution. If all the established hospital posts were filled (which is plainly not possible) we should I think find that many were redundant. Most teaching hospitals have more residents and registrars than the work warrants. Their posts are training posts. But must all this training be done at the teaching hospitals? Throughout the country there must also be a considerable number of experienced doctors, mostly ex-registrars, whom luck or inclination has not led into general practice.

2. To do laboratory or radiological investigations *before* the patient has been examined would in my view lead to a great waste of these facilities, which are already under great pressure.

3. General practitioners in their part-time rôle as clinical assistants can be of very great help in all the outpatient departments. But, economically speaking, they can be of little use in those positions where a continuous emergency service is required. They can never replace the resident surgical officer, the medical registrar, the obstetric registrar, the resident anæsthetist, the casualty officer, and the orthopædic registrar. In any of these positions at least six clinical assistants would be required to replace one resident, and even then there could be no satisfactory continuity in treatment and policy.

The provincial hospitals actually find it most difficult to find good doctors to fill these particular jobs. Good house-physicians, house-surgeons, and obstetric house-officers are not so scarce, because this type of resident job helps the prospective general practitioner.

Much has been written in the press recently about the unenviable job of the casualty officer. Further successful (or even unsuccessful) litigation against junior casualty officers will lead to extinction of the species.

The reasons why good registrars are difficult to come by in the peripheral hospitals are also widely recognised. A registrar post even in the best non-teaching hospital very rarely leads to senior-registrar and so to consultant status.

I would like to bring forward two suggestions which if found acceptable would do a great deal to improve the medical services given by the provincial hospitals:

1. The post of registrar should be abolished at all teaching hospitals. No senior-registrar jobs need be held outside teaching hospitals. The direct effect would be that the ambitious senior house-officer at the teaching hospital would be forced to spend at least two years as a registrar at a peripheral hospital before he could apply for a senior-registrar post at the teaching hospital. In this way the peripheral hospitals would get better registrars than many can get at present. These doctors themselves instead of often being largely supernumerary would get a very full practical training which would be completed academically after the return to the centre.

2. A new category of S.H.M.O. casualty officer should be created to take charge of the casualty room in every hospital in which the volume of work could carry such an appointment. The primary duty of this doctor would be to see each casualty patient at least once. If the patient is seen by a junior doctor in the evening then he *must* be referred to see the senior casualty officer next morning.

I believe there are sufficient experienced ex-registrars willing to take such posts, as they require experience and maturity of judgment but no higher qualifications.

Royal Albert Edward Infirmary,
Wigan. F. R. ZADIK.

TRICHOMONAS VAGINITIS

SIR,—Whatever may be the source of the infection in trichomonas vaginitis, it is certainly not the bowel. Refutations of the bowel hypothesis are to be found in the standard works on the subject, and a mass of evidence has been built up against it through the years.

Stabler, Feo, and Rakoff[1] inoculated cultures of the intestinal trichomonad, *T. hominis*, intravaginally. 50 patients were inoculated, 151 inoculations being made in all. Not only were these workers unable to produce vaginitis, but they also demonstrated that the protozoa could not even be recovered after a short interval. Subsequent vaginal inoculations with *T. vaginalis* produced a typical infection in 8 out of 10 of these patients.

An investigation carried out by American workers into the relative incidence of *T. vaginalis* in the vagina and *T. hominis* in the bowel in 200 women showed that, whereas 23% harboured *T. vaginalis*, in only 1% could *T. hominis* be demonstrated. This is surely not the result one would expect if the disease was "in most cases self-communicated" as Miss Landau (May 16) suggests.

Medicine and the Law

The State-aided Plaintiff

A CORRESPONDENT has taken exception to a few sentences in our leading article of May 2, where, in speculating on the causes of the undoubted increase in claims against medical practitioners and hospitals we mentioned the influence of the Legal Aid and Advice Act, 1949. The State aided plaintiff, we suggested, has his free run; 'State aided litigation tends to be fought to a finish without compromise'; the ordinary deterrents of having to pay his own costs and the costs of a successful defendant do not apply. Our correspondent's unfortunate experience contradicted this view. Though a State aided plaintiff, he found himself obliged to compromise his claim for a sum less than his disbursements. The Act and its attendant regulations, he found, imposed upon him a liability for payments to the Legal Aid Fund which came near to a threat that he might be made bankrupt even when he had succeeded in a claim brought on solid grounds.

His case indeed was hard; we may hope it was exceptional. He was claiming damages for professional negligence on the part of his family solicitors who had ignored a specific direction. When they denied liability, he put the matter into the hands of a second firm. He understood himself to be entitled to legal aid; the firm thought otherwise but, after reference to the Law Society, he was found to be qualified. The defendant solicitors offered to settle on the basis of some three-fifths of his claim. He was persuaded to accept this offer whereupon the defendants paid into court a very much smaller sum and the action went on. He was naturally indisposed to accept this smaller sum thus paid in; but his own solicitors warned him that, if the verdict he might obtain should not exceed that sum, he would be personally responsible for all the costs accruing after the date of payment into court.

Though this is not the place in which to set out, or even to summarise, the Act and regulations, it is certainly true that the new Legal Aid system is a flexible scheme which rightly seeks to satisfy the needs of the citizen and yet to protect the Exchequer and the taxpayer. In effect the State aided litigant makes what contribution he can to the Legal Aid Fund. If the assisted person wins, his position as regards costs is much the same as if he had received no legal aid; his unassisted opponent has apparently to pay full "party and party" costs—not merely 85% of them. The Fund has a first charge on any property, wherever situated recovered by or preserved for the assisted plaintiff. If the assisted person loses, his liability for the sum awarded is the same as that of an unassisted person who has lost. As regards costs, however, the Act limits his liability to "the amount (if any) which is a reasonable one for him to pay, having regard to all the circumstances, including the means of all the parties and their conduct in connection with the dispute." His house, his furniture, and the tools of his trade must be left out of account in assessing the amount of costs that he must pay. Under the regulations the court may order him to pay "such amount, if any, as the court thinks reasonable, having regard to all the circumstances." Much will depend on the interpretation given by the courts to that flexible word "reasonable." Meanwhile, in the phrase of the author of the leading textbook on the subject (himself an active participant in the framing of the new procedure), the privileges given by the provisions of the Act "may well provide an assisted person with a bargaining weapon of the 'Heads I win and tails you lose' variety against an unassisted opponent." That opinion, despite the converse experience of our correspondent, goes far to justify the general tenor of our previous statement.

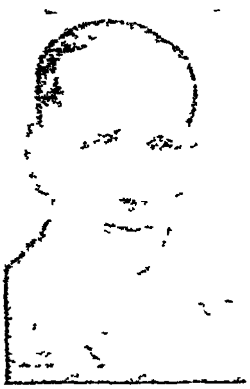
Obituary

KENNETH NORMAN ABBOTT HERDMAN

M A, M D Edin., D.A

Dr Herdman consultant anæsthetist to Leith Hospital who died on May 7 had approached his specialty by way of general practice. After graduating at the University of Edinburgh as M.A. in 1924 and as M B four years later, he held house-appointments at Leith Hospital a clinical tutorship at the Edinburgh Royal Infirmary, and a clinical assistantship at the Eye, Ear, and Throat Infirmary.

As a Territorial he was called up from his busy practice in Edinburgh at the beginning of the late war. He became a specialist anæsthetist at No 23 General Hospital in the Middle East then he went as anæsthetist to one of the units in the Eighth Army, the 15th (Mobile) Casualty Clearing Station. With No 15 he took part in the memorable advance from the Battle of Alamein along the North African coast to the end of the campaign at Cape Bon.



James Bacon & Son

Returning to civilian life he gave up general practice to concentrate entirely on anæsthesia and J. A. R, on behalf of his fellow-surgeons, writes

'Kenneth Herdman was one of those invaluable and all too rare doctors who specialise after a long experience in general practice. His experience in general medicine, and his gifts as a well-qualified and expert physician allied to his own sound judgment, gave him the power of accurately assessing patients' general conditions before, during and after operation. This was a great boon to his surgical colleagues, who sought his advice freely in the handling of their cases. They knew that his experience combined with superlative technical excellence, made him absolutely safe and reliable for their own work and also when need arose for themselves and their relatives.

"Tall gallant and debonair Kenneth Herdman never spared himself, and never complained, though his health had been precarious for some time. Ever considerate of others, it was characteristic of him that he was invariably punctual at all his engagements. This punctuality, with his unassuming cheerful efficiency, was particularly appreciated by the operating-theatre staffs with whom he worked. He was an outstanding man and he set us all a noble example of courage, unselfishness, and skill."

Dr Herdman leaves a widow and two sons.

CHRISTOPHER JOSEPH McSWEENEY

M.A. Dubl., M.D N U I, F R.C.P I, D.P H.

Dr McSweeney, medical superintendent of the Cork Street, Fever Hospital died on April 17 at the age of 54. A man of energy, ability, and character he was about to enter the most important stage of his life's work.

He was born at Cork and educated in that city at the Christian Brothers' College and at University College, from which he graduated as M.B with first-class honours in 1921. After holding an extern assistantship at The Rotunda Hospital, Dublin, he took the D.P.H., and in 1925 he was appointed assistant M.O H. for Cardiff where two years later he was promoted to be deputy M.O H. He also lectured on infectious diseases at the Welsh National School of Medicine.

In 1930 McSweeney took his M.D degree; in 1933 he became M.R.C.P I, and in the following year he returned to Dublin to take charge of Cork Street Fever Hospital. He brought with him a reputation for medical administration and during the years, through many vicissitudes he persisted in his purpose of providing new buildings for the hospital. The task was lately completed, and he moved his residence to the new hospitals only a few days before his death.

No-one working with these protozoa in the laboratory can fail to be impressed by the many wide differences they exhibit. *T. hominis* has entirely different growth requirements from *T. vaginalis*, and fails to grow in media which support a profuse growth of *T. vaginalis*.

Uncritical acceptance of the view that the infection originates in the bowel can only obscure the true facts and postpone fuller investigation of the actual means of transmission of this troublesome infection.

Liverpool. M. G. McENTEGART.

DIAGNOSIS OF ACUTE MENINGITIS IN INFANCY

SIR,—Dr. Haworth, in his article of May 9, rightly calls attention to the frequent absence of the "classical signs" of meningitis in infancy and to the necessity for early lumbar puncture. Recent emphasis in your leading article of April 11 on the hazards of lumbar puncture should not deter us from the use of this valuable diagnostic aid. The wide range of antibiotic and chemotherapeutic agents now available should further reduce the mortality. But how often is the hospital clinician needlessly handicapped by the indiscriminate use of these drugs which, in many cases, only result in disguising the clinical signs and making the identification of the causal organism difficult or impossible? In these difficult cases a full history from the general practitioner is always helpful, but what is probably more important is a detailed account of the treatment given prior to admission.

W. P. SWEETNAM
Halifax General Hospital. Consultant Pædiatrician.

DIET AND IMMUNITY

SIR,—Your leading article of May 9 ends with a statement for which there is surely little evidence. This statement reads:

> "... we can learn from the Scottish blackface ewes and their lambs that ... the most effective interval between injections of the antigen [A.P.T.] is two months, ... and that routine immunisation with A.P.T. should not be applied to infants during the first few months of life."

In one of the papers under review [1] it was shown that, with the particular dosage used in ewes, an interval of nine weeks between injections was definitely better than an interval of four weeks; but no other interval was tried. The optimum interval depends on the size of the dose and perhaps on the species of animal, and it is probable that an interval of three months can be regarded as best in the immunisation of young babies with A.P.T.[2] It was also shown [1] that a rough correlation existed between the total passive maternally conferred diphtheria antitoxin of lambs, and their response to the first and to the second injection of A.P.T. given in a course of active immunisation. Considerable if not total interference with the primary response was caused by the presence of sufficient antitoxin to neutralise half the A.P.T.

Evidence had previously, however, been published [2] showing that babies can be successfully immunised by two doses, each 0·5 ml. of A.P.T., if the titre of maternally conferred antitoxin is below 0·04 unit per ml. at the time of the first injection.

In recent unpublished work carried out at these laboratories and in collaboration with Dr. N. R. Butler of University College Hospital, we have been investigating the efficiency of three prophylactics in the immunisation of babies. All consisted of purified toxoid, partially or totally adsorbed on mineral carriers. Of 167 babies receiving the first injection at the age of about 1 week and the second injection either at 6 or 14 weeks, 161 (96·3%) had active antitoxin titres above the Schick level when measured at the age of 9 or 12 months. Of 115 babies receiving injections at the ages of 6 and 14 weeks, all but 1 had titres above the Schick level when 9 or 12 months old. This population was a random sample, 6·4% of whom had cord-blood titres of 1·0 unit per ml. or more, compared with 7·1% in 3000 samples of cord-blood tested here during the last few years.

From the evidence available, it would appear that a very high proportion of babies born at the present time can be satisfactorily immunised against diphtheria during the first few months of life, so long as a precipitated or adsorbed prophylactic is used. Attention has, however, been drawn to the fact that a large proportion of failures might follow the use of plain fluid purified toxoid, if the first of three injections were given at or before the age of 10 days.[3]

Wellcome Research Laboratories,
Beckenham, Kent. MOLLIE BARR.

INVOLVEMENT OF AUTONOMIC NERVE-FIBRES IN DIABETIC NEUROPATHY

SIR,—As Dr. Allwood and Mr. Burry (April 18) point out, it is not necessary to have a rate of heat loss as great as 240 kg. cal./hr./m^2 if only gross changes in blood-flow are to be estimated by means of skin-temperature measurements. It is sufficient if the extremity of a nude subject is placed in a cold box or if the extremity of the warmly dressed subject is exposed in a cold room.[4] Even under these conditions, however, the estimation of blood-flow changes in the feet by skin-temperature measurements may be especially difficult. In my own experience 25% of normal subjects show only a twofold increase in foot blood-flow (measured plethysmographically) in response to prolonged heating of the forearms and hands in water-baths at 45°C, and this increase may be too small to detect by means of skin-temperature measurement.

Pickering and Hess [5] found that it was sometimes difficult to produce vasodilatation in the feet, and they described one normal subject in whom they completely failed to produce vasodilatation (estimated by skin-temperature measurement). Because of this, failure to produce a marked increase in the skin-temperature of the feet, in response to warming the body elsewhere, has to be regarded with circumspection before it is interpreted as being due to autonomic involvement.

Even if one assumes that the skin-temperature measurements of patients with diabetic neuropathy are a reasonable reflection of the limb blood-flow, failure to produce vasodilatation in response to warming cannot be interpreted as being due to disease of the autonomic nervous system unless certain other possibilities are excluded. For example, occlusive vascular disease may be responsible for this effect, and the fact that 'Priscol' (tolazoline) may produce vasodilatation in patients suffering from diabetic neuropathy is not adequate evidence of the absence of vascular disease. It is quite conceivable that priscol may dilate a diseased artery although physiological stimuli will not. Disuse of the limbs with a consequent decrease in their metabolic activity and increase in their venous pressure may also affect the vasomotor reactions. Lewis and Pickering [6] have shown that the relative disuse of one limb even for half an hour will produce differences in the skin-temperature of the limbs which persist after warming the body. Similar differences are produced if the initial temperature of one limb is lower than that of the other.

It is for these and similar reasons that I suggested that Dr. Martin's conclusions (March 21) should be examined with caution.

Physiology Department,
St. Mary's Hospital Medical School,
London, W.2. A. McPHERSON.

6. Lewis, T., Pickering, G. W. *Heart*, 1931, 16, 33.

Meanwhile he was responsible for much of the teaching of his specialty He was lecturer in infectious diseases and deputy professor of preventive medicine at Trinity College, and consultant in fevers for the National Children's Hospital, Dublin He was examiner in fevers for the D P H, for the Dublin medical schools and to the nursing councils of Northern Ireland and Eire In 1936 he was elected fellow of the Royal College of Physicians of Ireland, and from 1937 to 1939 he served the college as censor

"Christopher McSweeney," writes J D, "had four main characteristics which were the foundation of his success He was an excellent teacher, clear and logical in his exposition and impressive in his manner with students and postgraduates He was an excellent clinician, with an encyclopædic knowledge of medicine and with a balanced and clear judgment He was a successful writer with a scholarly approach his book *A Clinical Approach to Fevers* was published two days before his death Lastly, he was a delightful person to know combining strong opinions with an easy tolerance of the views of others He was pleasant company and will long be remembered in Dublin for his wit His death at the beginning of the work of his great new hospital, and at the transition period during the reorganisation of the Irish health services, will be felt seriously in Dublin"

Dr McSweeney married in 1923 Miss Evelyn Harvey Donegan and they had one son

Dr L M ROSE

M J writes "Given only a few years more, Toby Rose would assuredly have made a place of note for himself in his chosen specialty Under a mask of casualness, which was sometimes apt to deceive his elders, he was a critical and most observant physician, who judged his own performance by rigorously perfectionist canons But he had other qualities which made him more than just a good clinician in a simply mechanical sense He was a man of taste, with fastidious and eclectic enthusiasms The natural temper of his mind was unhurried and traditionalist in outlook, and gave him a flavour somehow faintly uncontemporary His liking for old-fashioned forms was no dull conservatism but sprang partly from appraisal of their value as a discipline, and partly from appreciation that tradition at its best contains, for the subtle, a distinctive element of fun It was from this that his particular love of Oxford and for the Royal Navy—otherwise sufficiently dissimilar institutions—stemmed

"He was a gay companion and a good conversationalist who could easily make the small happenings of everyday life take on a vivid and amusing air He was a really brilliant mimic, and when he assumed the persona of his victim became instantly gifted with the power to parody his thought as well as the mannerisms of his speech It was characteristic that, throughout the months in which his last illness was making steady inroads upon his health, he said practically no word of it to anyone except in terms so vague and light as to rouse no suspicion of its gravity He was a brave man, and it is proper that we should mourn him"

Notes and News

WORLD HEALTH ASSEMBLY

THE sixth World Health Assembly, which opened in Geneva on May 5,[1] continued its discussions last week After he had been sworn in as the new director general of the World Health Organisation Dr M G Candau addressed the assembly The name of his predecessor, Dr Brock Chisholm had, he said, become identified during the last few years with the basic ideals of the organisation infinite respect for the dignity of man, wherever and under whatever conditions he lived clear and serene vision of the forces which would decide his fate, and unbroken determination to devote every day's energy and work towards the creation of a peaceful world in which the material, spiritual and cultural progress achieved by each nation would benefit all Dr Candau knew that he would justify the trust that had been placed in him if he was able to follow the path laid down by Dr Chisholm

At the first meeting of the committee on administration, finance, and legal matters, Mr M P Siegel, assistant director general, said that, as far as its regular budget was concerned, the organisation was in a wholesome financial position During 1952, 95% of the contributions due for that year from active member states had been collected But a serious situation had arisen, in the financing of the expanded programme of technical assistance for 1953[2] The total estimated cost of the year's programme had been set at $9,455,000, but the amount earmarked for W H O by the United Nations Technical Assistance Board was only $5,078,000 Wherever possible, therefore, new activities planned for the technical assistance programme had been postponed, and the utmost economy had been achieved in carrying on with existing schemes Generous help had been given by UNICEF, and certain projects had been transferred to the regular W H O programme As a result of these and other measures, it had not proved necessary to draw on the working capital fund to meet this serious difficulty

The committee on programme and budget adopted a resolution, to be placed before the assembly, which hoped that "longer term arrangements for financing future programmes will be made," and that in future the technical assistance programme would be planned in priority categories to allow for possible reductions in income

The assembly unanimously agreed to a request for membership from Nepal, which becomes the 80th member state of W H O The assembly also voted, by 43 to 6, with 13 abstentions, to welcome the return of the republic of China to active participation in the organisation, and to accept a lower assessment until her financial position had improved

THE DISABLED IN THE WORKSHOP

THE story of the Michael Works is one of splendid and undeserved failure Mr John Arthur, who founded this factory for severely disabled men in 1945, and was its manager, has now written an account[3] of the work done during its three years of independent life, the lessons learnt, and the results for the disabled men he befriended Of some 80 men who entered the works, no fewer than 40 were able to return to open industry

Mr Arthur's aim was to prove that men so severely handicapped as to be considered unemployable could often do as good a day's work as the able bodied, more—that they could maintain themselves economically, and need owe nothing to charity or public funds The Michael Works experiment demonstrated this beyond cavil When it was handed over to Remploy in 1949 the balance sheet showed that in each year of its operation it had paid its way It lost its independence only because it had too little capital to tide over the difficulties occasioned by the fluctuating purchase tax of 1948 Much had been learnt, however, not only about goods and markets but about disabled men and their response to opportunities for steady work

The second part of the book discusses the different kinds of disabilities these men were able to overcome—crippling rheumatism, cerebral palsy, deafness, amputations, epilepsy and tuberculosis Through the book runs Mr Arthur's sympathy and common sense, and his inspiration

HOSPITAL COSTING

SIR,—Dr. Avery Jones (May 16) expresses surprise at my two examples of hospital extravagances of bed-linen and farms and gardens. As regards bed-linen he says that there are important fallacies, for the reason that on stocktaking ward deficiencies are taken into account but not any excesses. This is news to me, as indeed is his statement that if a complete stocktaking of the entire hospital is taken on a single day these apparent discrepancies largely melt away. This is certainly not my experience. Apart from the point that there should be no excesses in wards, which itself indicates extravagant issuing, if Dr. Avery Jones will turn to p. 19 of the Health Service Accounts for 1951–52 he will see the words "including stock taking" and one assumes that this refers to a complete stocktaking, and not merely to wards. He says further, that "it does appear that the stocktaking system in hospitals needs overhauling." This presupposes that a stocktaking system already exists. Does it?

I agree with Dr. Avery Jones as far as gardens are concerned. They are essential amenities. But the gardens (and farms) referred to in the Auditor-General's report are not "amenity" gardens, which are included under the heading "Maintenance of Buildings, Plant, *and Grounds*," but gardens which exist for the sole purpose of providing produce which would otherwise be purchased. Farms are trading departments whether run by a hospital or a commercial concern, and the principle of business should therefore be observed. My point is that if the farms cannot be run without loss then hospitals should abandon them and purchase their supplies in the open market. They will find this method far cheaper. If Dr. Avery Jones wants a fallacy he will find it in the statement often heard, but never justified, that supplies from hospital gardens are better than those bought in the open market. "Amateur farmers" are a source of considerable extravagance to hospitals.

I welcome his point about bed occupancy. There is no doubt that much may be done to secure economies in this direction; but I question his statement that it is "perfectly feasible to achieve a 93% occupancy." It would be interesting to have the views of others on this point; I fear I have already taken up too much of your space.

ADMINISTRATOR.

SIR,—May I put in a plea for an old-fashioned method of securing economy which is in danger of being forgotten altogether? Having selected at each level of administration officials who are capable of exercising some judgment, is it not possible to allow them to do so? In other words, can we not get back to some measure of personal responsibility? One is a little sickened by the cowardice of the present system, in which an offender is seldom personally blamed but punishment by directive is visited on all for the defect of one.

If costing could trace wastefulness back to its source, it would show up the responsibility of the individual, but it is doubtful if such a degree of efficiency can be obtained. Costing is more likely to lose itself in a bog of false comparisons. It tends, too, to push up the standard of spending constantly, because those whose expenditure is about the average feel a comfortable complacence which encourages them to spend a little more, while those at the bottom of the scale feel a positive duty to catch up. In the modern hospital world the only real crime of administration is to fail to get your share from the hat.

If units of administration on every level were really allowed to handle their money, if an official knew that the success or failure of his budget was solely the concern of his committee and himself, "don't care" and "try it on" would disappear from the service. At present it is asking much of the most conscientious administrator not to fall back on them.

HOSPITAL SECRETARY.

SIR,—Writing about hospital costing last week, Dr. Avery Jones referred to the need for special study into the subject of bed occupancy and mentioned the possibility that this might be undertaken by an independent body. This subject, expanded slightly into the term "making the best use of the available beds," was the first special study chosen by the King's Fund Hospital Administrative Staff College; and work has been going on for more than a year. A number of experiments have been conducted during that time in hospitals of many different kinds, and it is hoped that a report will be issued by the early autumn.

ASCORBIC ACID AND GLUCOSE-1-PHOSPHATE IN RHEUMATOID ARTHRITIS

SIR,—The excellent paper by Dr. Lovell and his colleagues (May 16) was of especial interest to us, for we have also been investigating the action of glucose-1-phosphate in rheumatoid arthritis. In a pilot experiment, single doses of 25 mg., 50 mg., or 100 mg. were given intravenously to some 20 patients with rheumatoid arthritis. The clinical impression was that in some cases there was a transient improvement. A "double blind" experiment is now being made with photographic assessment[1] to see if the clinical impression can be confirmed.

It is clear from Dr. Lovell's paper that in the 4 cases investigated glucose-1-phosphate did not have an effect comparable with that of cortisone and that it is unlikely to prove useful as a treatment for rheumatoid arthritis. Our experiment is being continued for it is of some theoretical importance to see if there is any evidence that glucose-1-phosphate has a beneficial effect in some cases even though it be transient. We have already discussed[1] in some detail the difficulties in assessing the transient effects on rheumatoid arthritis of irregularly acting drugs and how the effects of rapidly metabolised substances may be missed.

The discussion by Dr. Lovell and his colleagues was very stimulating. They suggest that the means by which cortisone diminishes the tuberculin reaction may be different in the guineapig and in man. We would point out that, if the hypothesis of Long et al.[2] explaining the desensitising action of cortisone is true for the guineapig, then there is some evidence to suggest a species difference between the guineapig and man with respect to cortisone and ascorbic-acid metabolism.

Long et al. have suggested that cortisone desensitises by facilitating the oxidation of ascorbic acid to dehydroascorbic acid and that there is a shift of the equilibrium, ascorbic acid $\rightleftharpoons$ dehydroascorbic acid, to the right. But in man Stewart et al.[3] have shown that the ascorbic acid in the blood is partly in the dehydro form (20%) and that the effect of cortisone is that the dehydroascorbic acid vanishes without altering the total amount of ascorbic acid, which is then present only in the reduced form. This corresponds to a shift of the equilibrium to the left in man—the opposite of that proposed by the Long hypothesis in the guineapig. If there is a shift of the equilibrium to the right, a rise in electrode-potential (oxidation-reduction potential) would be expected; but we have shown[4] that in man cortisone causes a fall in the electrode potential of the subcutaneous tissues, corresponding to a shift of the equilibrium to the left—again the opposite of the supposed change in the guineapig.

We have also found in man and the rabbit that the intravenous injection of ascorbic acid produces a considerable

EXPERT COMMITTEE ON INFLUENZA

THE World Health Organisation recently set up an expert committee on influenza whose first session was held in Geneva in September, 1952 The report of this meeting is now published[1] The committee discussed a number of theoretical and practical aspects of the study, prevention, and treatment of influenza, and it has made recommendations on diagnostic procedures, collection and distribution of epidemiological information, and control measures Stress is laid on vaccination as the best method at present available for preventing influenza, but vaccination is still, in the committee s opinion, in the experimental stage, requiring further study and improvement Control measures against possible influenza pandemics and the many difficulties which might arise in this event are discussed This is a subject where there is room for more detailed recommendations on the control measures which are possible if a pandemic should arise in the near future and on research into alternative emergency methods Appendices describe technical details of laboratory diagnosis.

RESEARCH AND MENTAL HEALTH

LAST February the National Association for Mental Health held a stimulating conference on 'the practical application of research and experiment to the mental health field' At the time we were able to report some of the papers and discussions[2] Now—with commendable speed—the full proceedings of the conference have been published, and may be had from the association.[3] They read extremely well and will be useful for reference

Faculty of Ophthalmologists

The following have been elected officers for 1953–54

President Mr J H Doggart immediate past president Mr O M Duthie vice presidents Mr R C Davenport and Dr John Marshall hon. secretary, Mr E F King, hon. treasurer Mr E G Mackie

University of Sheffield

Dr P G Walker has been appointed a part-time honorary lecturer in biochemistry

Royal College of Surgeons of England

At a meeting of the council on May 14, with Sir Cecil Wakeley, the president, in the chair, Mr E Stanley Lee was admitted to the court of examiners, and Mr R V Cooke was re elected a member of the court Mr C Le Q Darcel and Dr L M. Franks were appointed as Imperial Cancer Research Fund lecturers

The Gilbert Blane medal for 1953 was awarded to Surgeon Captain J G Holmes (Alverstoke) for his work in the promotion of naval medical science and naval medical hygiene The Begley prize was awarded to R Danbury (Royal Free)

Prof F Davies (Sheffield) and Mr J Dobson (Wigan) were admitted to the fellowship having been elected as members of the college of twenty years standing A diploma of fellowship was granted to K D Shastri (Bombay)

Diplomas of membership and postgraduate diplomas were granted to those named in our report of the comitia of the Royal College of Physicians of London (*Lancet*, May 9, 1953, p 956)

The *Faculty of Anæsthetists* will hold the first examination for their fellowship in November Applications for examinerships are invited in our advertisement columns

Scottish Society of Anæsthetists

The following have been elected officers for 1953–54

President Dr W M Shearer Vice president Dr I M C Dewar Hon secretary Dr A G Miller, other members of the executive council Dr T J C MacDonald Dr H W C Griffiths Dr A Tindal Dr M Muir, Dr R Milne Dr M C MacQueen, and Dr R. G Grieve

The prize which the society is offering annually for the best paper submitted by a registrar was awarded to Dr F S Preston.

Papal Honour

The Pope has created Sir Daniel Davies a knight commander of the Order of St Sylvester in recognition of his services to the Roman Catholic Church and in particular to Cardinal Griffin and to priests and other patients at the Hospital of St John and St Elizabeth, London

International Congress of Hippocratic Medicine

This congress will be held at Evian from Sept 3 to 6 under the presidency of Professor Laignel Lavastine Further particulars may be had from Monsieur Paul Maubert Direction Cachat, Evian, Haute Savoie, France

Committee on N H S Costs

The committee which the Minister of Health has appointed to inquire into the cost of the National Health Service is now prepared to receive written evidence from persons and organisations Memoranda of evidence should be sent as soon as possible either direct to the secretary of the committee, Mr E Halliday Ministry of Health, Savile Row, W 1, or in Scotland via Mr R P Fraser, Department of Health for Scotland, St Andrew s House, Edinburgh, 1

Committee of Inquiry on the Rehabilitation of Disabled Persons

Any person or organisation who wishes to give evidence to this committee which has been set up by the Minister of Labour and National Service, the Minister of Health, and the Secretary of State for Scotland, under the chairmanship of Lord Piercy, should send to the joint secretaries of the committee Ministry of Labour and National Service, 32, St James's Square London, S W 1, a memorandum of the views they wish to put forward

N A P.T Canadian Exchange Scholarships

The Canadian exchange scholarships offered by the National Association for the Prevention of Tuberculosis have been awarded this year to Dr Bertram Mann, consultant chest physician at the Royal Halifax Infirmary, Yorkshire, who will leave England for three months in Canada early in September, and to Dr J J Laurier, assistant medical director of the Sacred Heart Hospital, Montreal, who has already arrived in England fall in the electrode potential of the subcutaneous tissues. This finding lends support to the suggestion that some ascorbic acid is normally present in the tissues in the dehydro form, for if it was all in the reduced form no change would be expected, the electrode potential depending on the proportion of the reduced to the oxidised forms and not on the absolute amount. Of course the situation is not as simple as this; for there are no doubt numerous other oxidation-reduction systems influencing the electrode potential, some of which may not react with the electrode.

TOXIC EFFECTS OF PHENYLBUTAZONE

SIR,—The common toxic sequelæ of phenylbutazone ('Butazolidin') therapy—gastric disturbance and occasionally hæmorrhage, dermatitis, and swollen feet due to salt retention—are as a rule not serious, and seldom occur unless the dosage is large. Patients with rheumatoid arthritis who do not show rapid benefit from 400 to 600 mg. (2 or 3 tablets) of phenylbutazone per day are probably better without it. Agranulocytosis, however, is a different problem because it can so easily be lethal. Here also it was hoped that there would be no danger with small dosage, except when the patient was sensitised by intermittent medication.[1] The case reported here shows that continuous administration of phenylbutazone in small dosage, even for a short time, may cause agranulocytosis, and that routine white-cell counts are useless. Even when symptoms of toxicity are noted and phenylbutazone is withheld, neither the total white-cell count nor the percentage of granular cells may give any indication of danger; the number of cells may decrease steadily after the phenylbutazone has been withdrawn.

In the present case there was an aplasia of all the marrow elements, reflected later in the decrease of hæmoglobin. The value of treatment with adrenocorticotropic hormone (A.C.T.H.) in such a case is still undecided, but antibiotic therapy and blood-transfusion were obviously essential. It therefore seems that the only precautions that can be taken against the dangers of phenylbutazone aplasia are to avoid intermittent dosage, especially with gaps of 10–20 days which may encourage sensitisation, and to warn the patient that any fever, malaise, or sore mouth or throat must be reported at once, when antibiotic therapy should immediately be started and the white-cell count watched. The clinical value of phenylbutazone in certain cases is such that with these precautions its use is justified, but its haphazard use is most dangerous.

A married woman, aged 46, with five months' history of rheumatoid arthritis, was admitted to hospital on Feb. 2, 1953, with involvement chiefly of the hands and wrists. The erythrocyte-sedimentation rate (E.S.R.) was 82 mm. in one hour (Westergren) and Hb 60% (8·9 g. per 100 ml.). Treatment in the first instance consisted of rest, physiotherapy, and intravenous iron from Feb. 11 to March 2, a total of 1·53 g. being given.

Phenylbutazone therapy was started on Feb. 16, and the patient took 1 tablet (200 mg.) orally twice daily, with good clinical response within a few days. After taking this dose for ten days she developed a patchy erythematous rash on the arms and chest, without other symptoms. On Feb. 26 the dosage was reduced to 1 tablet daily and 'Antistin' was given. On Feb. 27, the white-cell count was 13,200 per c.mm. (polymorphs 80%). The rash cleared after five days.

Five days later, on March 7, she complained of vomiting and diarrhœa, and next day the rash reappeared and the temperature rose rapidly to 103°F. The phenylbutazone was discontinued on March 9, but pyrexia and rash persisted, the latter becoming more extensive and papular. The mouth was dry and a little sore, but not ulcerated, and there was no sore throat. On March 12 the white-cell count was still normal—7500 per c.mm. (polymorphs 75%). On March 13, four days after the phenylbutazone had been stopped, the first signs of developing agranulocytosis appeared in the peripheral circulation. The clinical symptoms gradually improved, and from March 15 the patient was apparently well and symptomless. For eight days, from March 17 to 25, there were no polymorphs in the peripheral blood, and the white-cell count was 850–1900 per c.mm. During the same period the Hb decreased from 83% (12·3 g. per 100 ml.) to 58% (8·6 g. per 100 ml.). Examination of the sternal marrow on March 18 showed:

Polymorphs	0	Basophils	0
Metamyelocytes ..	0	Basomyelocytes ..	0
Myelocytes	16 %	Lymphocytes	20%
Myeloblasts	44 %	Monocytes	0
Eosinophils	10 %	Normoblasts	1·5%
Eosin-myelocytes ..	0	Hæmocytoblasts ..	9·5%

Peroxidase-positive 26 %; Peroxidase-negative 74 %
Megakaryocytes increased but no mature platelets budding off.

The findings indicated a toxic arrest of development of red cells and neutrophils.

From March 12 the patient was given procaine penicillin 600,000 units and aureomycin 750 mg. daily. Two days later therapy with A.C.T.H. 75 mg. daily was started. This dosage was reduced to 50 mg. after two days, and to 40 mg. after a further eight days. Two blood-transfusions, each of 2 pints, were given on the fourth and eighth days of agranulocytosis. On March 25, a day after the second transfusion, a white-cell count showed polymorphs 6% in the peripheral blood and the Hb increased to 83% (12·3 g. per 100 ml.). Thence onwards the numbers of white cells, including polymorphs, continued to increase, and on April 2 the white-cell count was 14,800 per c.mm. (polymorphs 78%) with Hb 94%.

The patient's rheumatoid condition did not deteriorate either on reduction of the dose of phenylbutazone or when it was discontinued. She had no rheumatic symptoms from the time the temperature and general

West London Hospital Medical School

Sir Clement Price Thomas will deliver the Alex Simpson Smith lecture at 11, Chandos Street, W 1, on Thursday, June 11, at 4 30 P M He will speak on Benign Tumours of the Lung

Indian Medical Service Dinner Club

The annual dinner of the club will be held at the Connaught Rooms, Great Queen Street, London, W C 2, on Friday, June 26, at 7 30 P M Tickets may be had *from the hon secretary* of the club, Medical Board Room Commonwealth Relations Office, Matthew Parker Street, S W 1

University College, London

Madame S Filitti Wurmser of the University of Paris will deliver two lectures at the college, Gower Street, W C 1, on Tuesday and Wednesday, June 9 and 10, at 5 P M She is to speak on the Physical Chemistry of an Immunological Reaction The first lecture is entitled Étude quantitative de l'isohémagglutination humaine, and the second Les isoagglutinines anti B de divers génotypes

United Hospitals Festival Choir

This choir, which is made up of members of the medical, nursing, administrative, and technical staffs, and students from over 60 hospitals in the Greater London area, is giving a performance of the *Messiah* in the Royal Festival Hall on Wednesday, June 24, at 7 45 P M They will be accompanied by the London Symphony Orchestra The proceeds of the concert will be given to the British Commonwealth and Empire Nurses War Memorial Fund Tickets may be had from the Royal Festival Hall box office

Chelsea Clinical Society

At the annual dinner on May 12 the toast of The Society was proposed by Archimandrite James Virvos, provost of the Greek Cathedral, who remarked that everyone wants to be on good terms with doctors but prays never to be treated by them The medical men of modern times had much in common, he said, with those of remote antiquity, and in those days Homer was already describing the doctor as a man worth many others Hippocrates employed the science of comparative observation and used the method of deduction which protected him from speculation, and his work and teaching showed an integrity that justified his title as the Father of Medicine The modern medical society was a link with the ancient Greece, the cradle of medicine Responding, Mr Eric Steeler, the president, spoke of the miracle of Athenian civilisation, developing within the short space of four hundred years, and of the way that in modern times Greece had kept open the gateway of freedom Turning to the society's affairs he was able to report an instructive year, which had included a notable discussion on juvenile delinquency a memorable address by Sir William MacArthur, and a cheerful evening when Mr Gilbert Harding revealed new sides of his personality Mr D N Matthews then dealt faithfully and wittily with The Guests at what he called ' this our annual gastro enterological meeting " Recalling that the gods destroyed Asclepios with a thunderbolt because they jealously thought him too good a physician, he saw no reason to suppose that the lack of thunderbolts today was due to any lack of watchfulness on the part of the celestial authorities Sir Ernest Gowers, in reply, spoke of old days in his father's house, when he used to watch the sheep and cattle being driven up Queen Anne Street on their way to Smithfield In his early youth he had learnt that the medical profession were the elite of the world and all the rest were *merely patients* One of the characteristics of the profession was that its members did not like entrusting their affairs to laymen, but in the end they always won—because, of course, they were always right In adding his thanks on behalf of the guests, Sir Cecil Wakeley, P R C S, did not put forward the same claim

Mr Steeler as outgoing president then bestowed his badge of office upon his successor Dr J N Loring

L. MANDEL.

SIR,—In view of the recent correspondence about toxic and sometimes fatal effects of phenylbutazone the following report of two cases developing agranulocytosis may be of general interest.

CASE 1.—Mrs. A, aged 26, had had rheumatoid arthritis of hands, feet, and knees, with attacks and remissions, for over three years; and ulcerative colitis with attacks and remissions for three years. Almost invariably the two conditions alternated—a period of active colitis bringing relief of arthritic signs and symptoms, and a remission in the colitis being spoilt by activity in the arthritis.

In August, 1952, for the first time both conditions were active together, and her condition was very unhappy. By October the colitis was under control, but the arthritis was very disabling. Orthopædic help—manipulation and plaster splints for the ankles—was needed.

Perhaps inadvisedly (on account of the intestinal lesion) treatment with phenylbutazone was started on Oct. 21 (1 g. intramuscularly daily for ten days, followed by 1·2 g. by mouth daily for eighteen days).

There was improvement both in pain and swelling after the first few injections, and the improvement was maintained. But just before the month was up she felt rather low and a bit nauseated, and she became jaundiced with an enlarged tender liver. The phenylbutazone was stopped, but during the next week she had an ulcerative stomatitis and was found to have a total polymorph-count of 28 per c.mm. Penicillin and pyridoxine were started, and fortunately recovery from the agranulocytosis was rapid; within one week she had 4000 polymorphs per c.mm. The jaundice persisted for two to three weeks, but cleared entirely, and the liver returned to normal size. The patient is now in good form, though still using walking plasters.

CASE 2.—Miss B, aged 43, had suffered from rheumatoid arthritis for ten years, and during this time had received courses of physiotherapy, two courses of gold injections, and autogenous vaccine therapy at other clinics. In June, 1952, her arthritis flared up following a urinary-tract infection which was controlled by chemotherapy. After a short remission, there was further swelling of the wrists and one ankle, and the erythrocyte-sedimentation rate rose to 65 mm. in the 1st hour. She was anxious to try phenylbutazone, and as her initial white-cell count appeared within normal limits (Hb 72%; white cells 5250 per c.mm., polymorphs 56%), we decided to begin treatment with 0·2 g. t.d.s. (together with oral iron and vitamin supplements) on Oct. 27.

She had immediate relief from pain, although there was no demonstrable reduction in joint swelling or other signs. An attempt to reduce the dose produced an increase in her pain, and the dose was therefore again increased to 0·6 g. daily at the end of November.

In December she developed an upper respiratory tract infection with a low pyrexia of 99° to 100°F. Phenylbutazone was stopped and she was treated with penicillin, followed by chloramphenicol, without effect. In view of this failure to respond, she was admitted to hospital, where her blood was found to contain only 400 white cells per c.mm. (lymphocytes 98%). Her general condition was otherwise surprisingly good; in spite of massive doses of penicillin (later combined with aureomycin, pentnucleotide, and pyridoxine) she did not respond to treatment; her white-cell count fell to 200 per c.mm. (all lymphocytes) and pyrexia continued. A transfusion of fresh blood failed to help, and she died five days after admission from terminal bronchopneumonia, resulting from agranulocytosis.

At necropsy the sternal marrow appeared pink and healthy, and showed evidence of a return to normal activity. Although the spleen was slightly enlarged, it seemed unlikely that this was, in fact, a rheumatoid hypersplenism, since earlier white-cell counts had always been within normal limits, and quite unlike the picture accompanying Felty's syndrome.

Reviewing the first case, it seems that perhaps the presence of ulcerative colitis should have excluded the use of phenylbutazone; the daily dose of the drug and the length of treatment were greater than those now generally employed. This comment also applies to the second case, but an attempt to reduce the dosage and length of treatment was strongly resisted by the patient.

We have since obtained good results in other cases with smaller doses—e.g., 0·2 g. t.d.s., reducing within a few days to 0·2 g. b.d., followed by a further reduction as soon as possible.

In our opinion only uncomplicated cases should be treated as outpatients, and a white-cell count should be carried out initially and repeated at intervals of three days for the first week or two. Thereafter, and even during the preliminary stages, the responsibility for reporting every minor symptom such as a sore throat, skin rash, icterus, or febrile reaction should be placed firmly upon the patient. To do this, the patient must be guaranteed immediate access to the clinician in charge (or his representative) by means of a printed note which mentions the common toxic symptoms, and advises the patient to report to hospital on any suspicion that he or she may be the victim of an unfavourable reaction; a similar procedure is adopted with patients on thiouracil, troxidone, and other potential marrow toxins.

Patients who have any obvious complication—e.g., gastro-intestinal, hepatic, or endocrine dysfunction, or abnormal hæmopoiesis—which would make them unusually sensitive to the drug should certainly never be treated as outpatients, if at all.

General Hospital,
Nottingham.

THE TRAINING OF NURSES

SIR,—The General Nursing Council's desire to close the Fevers Register has produced great concern among those engaged in the management of infectious diseases, whether as hospital physicians or public-health administrators. It might be concluded that this is simply due to the formidable problem which staffing of their hospitals will present. But to some of us this is not the only, or indeed the main, cause for concern. It in large measure arises from the belief that the whole direction and emphasis of nurse training is proceeding without regard to the needs of the community.

Up till the emergence of that strong and fearless character, Florence Nightingale, nursing as we know it was non-existent. The value of her reforms lay not least in the persuading of the medical profession of the benefits to be obtained from an efficient and honourable nursing service. And, during the latter part of the 19th and first part of the 20th century, the training of nurses was felt as a concern (in the old Quaker sense) by even the most senior medical men, who took a large part in the teaching and administrative affairs of nurses. During the last twenty years the nursing profession has very properly increasingly organised itself; but one unfortunate result both of the great improvement in the quality of the nurse and of the development of the nursing profession by its own seniors has been the lessened interest of the medical profession, perhaps particularly in its junior ranks. I believe that it is true to say that the proportion of hospital doctors who feel a personal sense of participation in the training of nurses is now much smaller than it was twenty or thirty years ago.

It is natural that a profession should display a desire for the continued improvement of its stature; but there are good reasons for suggesting that the development of the nursing profession must be circumscribed by the needs of the community. The kind of nurse the community trains should be the kind of nurse that the community requires. No matter how desirable a certain reform may seem, its adoption must always defer to this overriding question: "Will it result in producing the kind of nurse who will best serve the community?"

The great medical and surgical advances of the last twenty years have demanded a high level of nursing

(Concluded from p 1018)

Medical Treatment

Not all patients with mitral stenosis require treatment, and, when the diagnosis is made, the most important question to be decided is whether anything need be done about it In the absence of symptoms, treatment with drugs and restrictions other than advice against the pursuit of an unsuitable occupation are rarely necessary When there is undue dyspnœa on exertion or a severe symptom such as paroxysmal dyspnœa or hæmoptysis, it is best to avoid the amount of exertion that brings it on Though in patients with a progressive disability cardiac failure may be postponed by suitable restrictions, it is almost equally important, by not imposing excessive restrictions, to avoid the unnecessary invalidism and unhappiness which these patients often experience, and to prevent cardiac neurosis Advice may be needed regarding pregnancy because the increased load on the circulation may prove too great a burden for a diseased heart

When auricular fibrillation develops, as it usually does in patients who have progressive disability, digitalis will be required to control the heart-rate Before signs of cardiac failure are manifest, digitalis does nothing to relieve dyspnœa and its administration is not only valueless but also harmful Apart from its action on the heart it is a vasoconstrictor In some patients it appears to precipitate the onset of auricular fibrillation It is of no value in the management of sinus tachycardia unless there is cardiac failure Since it is known to be a "heart drug," the patient may gain an exaggerated impression of the gravity of her illness It is true that, when cardiac failure is imminent, it may be difficult to discern when the borderline has been reached, and then a short therapeutic trial of the drug is justified After the onset of cardiac failure full digitalisation must usually be continued for the rest of the patient's life, unless failure has been precipitated by some transient factor such as an acute respiratory infection If digitalis is not sufficient to control the failure, injections of mercurial diuretics and restriction of sodium intake may be needed

Intercurrent acute infections should be promptly treated Respiratory infections are common in patients with mitral stenosis, and may be responsible not only for part of the dyspnœa but also for the onset of cardiac failure The importance of not mistaking pulmonary congestion and œdema for acute bronchitis has already been emphasised

Watch should be kept for subacute bacterial endocarditis, and this diagnosis should be considered in any obscure fever lasting for more than a few days

Recurrence of rheumatic fever is most common in the first year after the initial attack, and something may be done to prevent this, particularly in young people, by the daily administration of sulphonamide or penicillin

ACUTE PULMONARY ŒDEMA

The patient should be reassured, made comfortable with pillows in the upright sitting posture, and given an injection of morphine (preferably intravenously) gr $^1/_6$–$^1/_4$ (10–15 mg) If possible, oxygen should be administered Unlike attacks of left ventricular failure, acute pulmonary œdema does not respond to digitalis If there is bronchospasm, aminophylline 0 25–0 5 g may be given by slow intravenous injection Should these measures not suffice, pressure cuffs should be applied to the thighs as far proximal as possible with the object of temporarily diminishing the venous return to the right auricle Intertracheal suction may be needed to remove excessive secretion, but this must be done with the patient upright On no account must she be laid flat

Classification

We have found it unprofitable to classify cases of mitral stenosis according to their severity, for there is no good way of weighing one contributory factor against another Limitation of physical activity is the basis of the following classification recommended by the American Heart Association

Class I —Without limitation of physical activity Ordinary physical activity causes no discomfort

Class II —Slight to moderate limitation of physical activity Ordinary physical activity causes discomfort

Class III —Moderate to great limitation of physical activity Less than ordinary physical activity causes discomfort

Class IV —Unable to carry on any physical activity without discomfort

But this is not a satisfactory gauge of severity in patients with rheumatic heart disease Those who are relatively little disabled by dyspnœa on exertion may be subject to dangerous attacks of pulmonary œdema They vary widely in their standards and in their tolerance of discomfort, and in some of them superimposed anxiety or neurosis is difficult to assess The degree and duration of each valvular defect and of myocardial damage, and the presence or absence of auricular fibrillation, all modify cardiac function Some factors balance each other for a time Pulmonary arteriolar resistance protects the lungs from pulmonary œdema but puts a severe strain on the right ventricle and leads to its eventual failure

Indications for Surgical Treatment

Operation should be considered in every case in which the diagnosis of mitral stenosis is made In many the possibility can be readily dismissed, in others the decision can be reached only after full investigation, while in others again the indications may be clear The ideal cases for valvulotomy are those with a severe valvular lesion and little damage to the myocardium The hearts of these patients are not large, though the characteristic pattern of mitral stenosis is apparent on radiography (fig 3)

Operation has not been advised in patients who have no symptoms whatever Indeed few patients with mild disability have yet undergone operation But it is in the latter group that the operation may eventually prove most useful, because it may prevent severe symptoms from developing On the other hand it is possible that if an operation is performed too early it may have to be repeated at a later date Time alone can show whether this is so

Most difficulties arise in advising those patients who have had prolonged severe disability—the "chronic mitrals" They have abandoned hope of spontaneous improvement, and understand only too well that treatment with rest and drugs is palliative, and that ever-increasing discomfort lies before them Some patients with very large hearts have been accepted for operation because it was thought that the state of the myocardium might allow improvement if obstruction was relieved It is in this group that operation carries the greatest risk

Paroxysmal dyspnœa, pulmonary œdema, and recurrent hæmoptysis are strong indications for valvulotomy Embolism is more debatable technique; but it would be dangerous to conclude from this that *all* those who wish to qualify for the designation "nurse" must of necessity reach this high standard. There is still, and there always will be, a real need for the "bedside" nurse who is highly trained in the practical duties of nursing. The requirements of the community make it necessary, I believe, to contemplate two spheres of nursing. All who enter the profession must qualify by undergoing a basic course of training; those who aspire, by reason of special interests or aptitudes, to the highest ranks would require to undertake further training. It might be argued that this principle has already been conceded by the recent introduction of the grade of assistant nurse. But the term "assistant nurse," as at present used to describe those who have taken something similar to a basic nursing course, is an erroneous one and its implication of inferiority is unfortunate.

It should be possible, as you suggested some years ago,[1] to define a "basic nursing course" which would constitute the warrant for the designation State-qualified Nurse (S.Q.N.). Such persons should be able to be trained in *any* hospital which comes up to a certain preordained and strictly exercised standard. The duration of such training should, I think, be one year, followed by a further year working as a nurse in an approved hospital. The best material which passed through this basic course would be attracted to specialise in general, surgical, medical, infectious-disease, mental, and children's specialties, and it would be from those who have taken such special courses that the ward sisters, theatre sisters, &c., would come. These State-qualified nurses would constitute the body of the hospital nursing strength, working as nurses under the more highly trained sisters. The nurse-in-training could then be regarded more correctly as a student and as only a part-time worker in the ward routine.

The controversy over the Fevers Register has brought more sharply into focus the serious hazard to which a health service may be exposed if attention is directed solely to the training of more highly qualified nurses. Anyone who examines the content of the student nurse's curriculum must reach the conclusion that there is a danger that the modern general nurse is being transformed into a kind of unsatisfactory medical student, unbalanced by possession of a pseudoscientific mental equipment, while the real needs of the service and the public are neglected.

Department of Infectious Diseases,
University of Glasgow.
THOMAS ANDERSON.

INTRA-ARTERIAL TRANSFUSIONS

SIR,—I am prompted to write to you by Professor Schaeffer's letter (May 9) describing an apparatus to prevent air-embolism in intra-arterial transfusion. It may be of interest to your readers to know that an essentially similar piece of apparatus was described in your columns[2] in 1941, and has been available from Medical and Industrial Equipment Ltd., 12, New Cavendish Street, London, W.1, for some nine years.

Newcastle upon Tyne, 2.
A. MACKENZIE.

SIR,—In the intra-arterial transfusion outfit described by Professor Schaeffer, the essential part of the instrument is the glass float inside the drip chamber, which prevents air embolus. This drip chamber and its glass float were first described by Macintosh and Pask[2] in the *Lancet* in 1941, and again illustrated by myself in 1945.[3] It has become widely known in this country, if not the world, since that time under the name of the Oxford Safety Dripper.

Department of Anæsthetics,
Royal Infirmary, Cardiff.
W. W. MUSHIN.

Parliament

THE N.H.S. INQUIRY

Debate in the Commons

SPEAKING on a token vote on the Health Estimates on May 18, Mr. ANEURIN BEVAN said that, though it was reasonable for an inquiry to be held into the National Health Service, he could not understand why the Minister had not used the Central Health Services Council, which had been appointed to advise him not only of any changes which might be necessary but of any defects which might be thrown up in experience of the administration of the service. Why had the Minister then set up an independent committee? Could it be to obtain an alibi to cut the service? The terms of reference suggested that the committee were to advise the Minister how the funds made available by the Exchequer were to be apportioned. In Mr. Bevan's view *priorities of expenditure inside the* service were social priorities and were a matter of political opinion and judgment.

The expenditure in the two parts of the N.H.S. where the patient initiated expenditure—i.e., the dental and ophthalmic services—had begun to fall once the initial backlog of neglect was worked off. On the pharmaceutical side the picture was slightly different. Here the initiative in expenditure lay mainly with the doctor, not the patient. On that side expenditure was still rising despite the shilling charge. It was surely a reflection on the medical profession that last year we spent £400,000 on 'Dexedrine' when the equivalent in the official formulary would have cost about £158,000. But for this *we should not penalise the patient but investigate* the profits of the big drug houses and stiffen more severely the discipline over the general practitioner.

Though Mr. Bevan agreed that there were questions of priority to be settled both inside and outside the service, he did not see that the Guillebaud Committee was the body to do it. It might be that the Central Health Services Council were too deeply involved in the administration of the N.H.S. to take an objective view. But the House of Commons was an opinion-making body and it was nonsense to ask an outside committee "What do you think our opinion should be about this?" That was why he stuck to his words that it was cowardice to set up a committee. If the Government wanted to cut the health service, why did they not say so instead of calling a committee into existence and hoping to hide behind it.

THE MINISTER'S SPEECH

Mr. IAIN MACLEOD, Minister of Health, said that the appointment of the committee had been greeted with almost universal approval in the press. Two questions to be decided were: Was there anything to inquire into? and, if so, who should undertake the inquiry? On some matters within the area of dispute he wanted advice, though he agreed that the decisions could be taken only by the House of Commons. Giving examples of the matters on which he wanted advice, Mr. Macleod said it was one view that the central accounting system of this country was never designed for the burden that the health service had put upon it in the management of several thousand hospitals. There would be great economies if the hospitals could plan three or five years ahead. If the block grant was to be effective they must be reasonably certain of stable prices for some years ahead. Ambulances were a hospital service in Scotland and a local-authority service in England: which system was the better? Had local authorities found their right rôle in the health service?

Mr. Macleod felt that, after five years, there was an unanswerable case for some investigation. He desired an independent view from independent-minded people not tied either to the professions or to political parties. Expenditure in the health-service field could not be controlled unless man-power was controlled, because salaries and wages accounted for two-thirds of the cost of hospitals, and hospitals accounted for nearly two-thirds of the cost of the scheme. They must try to relate the numbers employed to the service obtained and he hoped that as an outcome of the inquiry more staff might be available for the hospitals and sanatoria which were at present in the greatest need.

In general it may be said that operation is advisable whenever there is considerable or progressive disability, and none of the contra-indications referred to below is present

Contra-indications

AGE

The youngest patient operated on in this series was sixteen years of age The principal indications in her case were attacks of pulmonary œdema and recurrent hæmoptysis Now, eighteen months later, she declares that she has no disability

In youth there is a greater risk of further attacks of rheumatic fever, and therefore of increase or recurrence of mitral stenosis, than in later years, but this risk would not justify the denial of valvulotomy to a child whose life was endangered by the mechanical effects of mitral stenosis Except when the disability is severe or rapidly increasing, and clearly the result of obstruction at the mitral valve, it is probably better to delay operation until about the age of twenty

14 patients were over fifty, the oldest being fifty-nine We have found the behaviour of the heart at operation less good in patients over fifty

SEVERITY

Too Mild

Mitral stenosis without symptoms or a history of rheumatic fever is often diagnosed at some routine examination such as that for National Service or life assurance The physical signs of valvular disease may be obvious and pathognomonic, but there is little or no evidence of cardiac enlargement and none of cardiac insufficiency In many of these patients the condition will be judged too mild for valvulotomy, and it may remain benign throughout a life of normal span These patients should, however, be kept under observation for evidence of progression Only in this way can be selected the ideal time for valvulotomy as a prophylactic measure in mitral stenosis

Progression is best judged by the patient's own account of the symptoms To wait for an increase in objective signs will usually be to wait too long

When there is doubt as to the degree of severity in this group, additional help may be obtained from cardiac catheterisation A normal or slightly raised pulmonary arterial pressure at rest, with little rise on exertion, probably confirms that the obstruction is slight Calculation of blood flow is necessary for precision In the few patients in whom the resting mean pulmonary arterial pressure has been in the upper range of normal or slightly above (15–20 mm Hg), and the rise of pressure on exertion has been small (10 mm Hg), a significant, although not a severe, degree of stenosis has been found at operation

Too Severe

There is no need to describe in detail the manifestations of advanced rheumatic mitral disease In many patients the condition has progressed too far for operation to be of value Gross enlargement of the heart, recurrent or intractable cardiac failure, and cardiac cirrhosis of the liver are evidence of such severity These patients have not only mitral obstruction but also so much damage to the myocardium that, although the mechanical obstacle to an adequate cardiac output is relieved and some benefit must accrue, this may not be commensurate with the risk involved They must nevertheless be considered carefully, because they have no prospect of improvement without operation

ASSOCIATED VALVULAR LESIONS

Mitral Incompetence

Predominant mitral incompetence will contra-indicate valvulotomy until it is possible to introduce an adequate supplementary mitral cusp We have not observed the diminution of regurgitation by valvulotomy alone Possibly, when significant stenosis is also present, the total disability may be reduced by valvulotomy and consequent relief of obstruction, even if the degree of regurgitation remains unchanged The importance of a regurgitant stream felt immediately after valvulotomy is variable

The diagnosis of predominant mitral incompetence accompanying mitral stenosis may be very difficult The various points which are of importance have been discussed previously (Logan and Turner 1952b), but may be summarised as follows

In the absence of aortic valvular disease (whose significance must be assessed on peripheral rather than cardiac signs) and of systemic hypertension, any evidence (clinical, radiological, or electrocardiographic) of hypertrophy or enlargement of the left ventricle suggests that there is significant mitral incompetence A loud harsh mitral systolic murmur supports the diagnosis but may be misleading Systolic expansion of the left atrium observed at fluoroscopy is an unreliable sign The pulmonary capillary-venous tracing obtained at cardiac catheterisation may give supporting evidence but is often of no value A clear first heart sound and "opening snap" rarely accompany predominant incompetence

We believe the clinical examination is more important than accessory methods in this admittedly difficult differential diagnosis No method should be neglected, and attention to all the evidence should enable errors to be avoided

Aortic Incompetence

The diagnosis of aortic incompetence is made by hearing the characteristic long, blowing, high pitched early diastolic murmur which begins immediately after the second heart sound, is best heard along the left sternal edge, and is often audible at the apex and to the right of the upper sternum The significance of this murmur cannot be judged from its intensity or duration but depends on the peripheral signs of aortic regurgitation—a collapsing arterial pulse, an increase in the pulse pressure, and abnormal pulsation in the aorta seen on X-ray examination In the absence of significant mitral incompetence or systemic hypertension left ventricular enlargement or hypertrophy can be attributed to aortic incompetence Enlargement of the left ventricle can be observed radiologically long before there is electrocardiographic evidence of hypertrophy

Of this series of 100 patients subjected to valvulotomy, 30 had signs of aortic incompetence We have operated on only 2 patients with aortic incompetence complicating mitral stenosis in whom there was electrocardiographic evidence of left ventricular hypertrophy, and both did well 6 of the 30 have had radiological signs compatible with left ventricular enlargement, but reference has already been made to the difficulty of differentiating this from right sided enlargement

Palpation of the cardiac impulse at the apex is a good guide to left ventricular hypertrophy The heave may be unmistakable when there is still no radiographic enlargement In aortic incompetence enlargement of the left ventricle may become obvious in the postero anterior view earlier than in the left anterior oblique view

We have regarded severe aortic incompetence as a contra indication to operation for associated mitral stenosis Mild aortic incompetence has been ignored Difficult cases lie between these two extremes When tight mitral stenosis and considerable aortic incompetence occur together, as they often do, there is no a priori reason for withholding valvulotomy In uncomplicated aortic incompetence a surprisingly great degree of regurgitation may be found without symptoms The left ventricle may not fail for many years Associated mitral stenosis may be difficult to assess, but, unless aortic

The Government viewed the present cost of the pharmaceutical services, as did their predecessors, with the greatest concern. It was the only part of the health service which was not under financial control at present. Prescriptions were now running at the rate of 241 million a year in Great Britain, and the average cost of a prescription had climbed from 38*d*. in 1949–50 to 40·5*d*., 47*d*., and 50·7*d*., and he had made an estimate of 52*d*. for each prescription for this year. The rise was due to a general increase in ingredient costs, although that was flattening out, to the increasing use of new, valuable, and expensive drugs, and to the important increase in the proportion of proprietaries. The increase of 3½*d*. last year in each prescription was mainly due to large quantities being supplied. Before the health service was introduced the proportion of proprietaries was 6%: it was now 25%, which accounted for about half the drug bill, and the whole of the amount he had to pay out, taking into account the hospitals, was about £60 million.

In a month or so, when the final arrangements were made for the two schedules laid down by Sir Henry Cohen's committee, which referred to drugs not of proved therapeutic value, doctors were to be asked not to prescribe them. But the biggest problem was that 4000 proprietaries came in the categories which the Cohen committee advised were not superior to standard preparations but which they thought ought to be prescribable, subject to satisfactory price arrangements being made. The problem, which was not a new one, was what was to be done in this matter. There was a genuine case for many of these firms, but the trouble was that there were firms who were merely wrapping up standard preparations in pretty packages and forcing them on the notice of doctors by salesmanship. The Government had decided to start a number of investigations into the cost of manufacture of certain of these proprietaries, which seemed at first sight to be specially expensive. He hoped this would yield substantial savings. In due course he would circulate to doctors the names of those preparations concerning which satisfactory agreements on prices had not been reached. This action should not be taken to be the end of the story, and he did not rule out more drastic measures if this should fail.

Discussing the charges, Mr. Macleod related that the 1*s*. charge in the first month caused a drop of 14% in the number of prescriptions, but by September the deterrent effect was ¼%. The dental charges for adults had led to a slight fall in conservative treatment, while the number of children's courses for the last quarter of 1952 was 170,000 as against 350,000 in 1950, and they comprised 22% of the courses under the N.H.S. in 1952 as against 9% in 1950. The number of school dentists had risen from 812 in January, 1951, to 998 in January, 1953.

For the first time since 1946, he continued, there was now a genuine measure of priority for the priority classes. The main problem was how to meet the thrusting needs of the hospital service. Last year the hospitals underspent by £14 million owing partly to the Government's requests to them not to overspend and partly to the fact that the Government for so many months held the cost of living virtually stable. In this year's estimates £15¼ million extra had been provided for the hospitals, and, adding certain other sums to this total, he was providing £20 million over the out-turn for the last year for that purpose. No-one could say that there had not been coöperation with the Chancellor of the Exchequer in finding the money. With this £20 million he could maintain the service, bring into full use developments which had been finished recently, and provide for modest future development.

Mr. Macleod admitted that if the Chancellor offered him more money he would not look to free dentures and free medicines but to the mental health of the country. But he agreed that the policy of successive charges would in time destroy the service. He did not know if we were at end of charges, but at least we had called a halt. What we wanted to achieve was a system by which the service had an interest in economy which was as natural and rewarding as was its interest in medical efficiency. That was the essence of the problem which the Guillebaud Committee was trying to solve.

FURTHER DEBATE

Mr. **Arthur Blenkinsop** suggested that in the Minister's view there were two sections of the community—one which might reasonably be expected to pay charges and the other which might be expected to receive the benefits. The richer section of the community might use the social services, but they paid more in rates and taxes than the benefits they derived. Thus the social services were the responsibility of the rich in so far as these were willing and able to make some extra provision out of their resources to provide benefits for the poor. To Mr. Blenkinsop it seemed that this paternal approach was bedevilling the service. It took no account of the interdependence of all sections of the community. By imposing charges we were asking that the whole provision of our social services should be directed to one section of the community, who were assumed to be unable to pay for the benefits they received. Yet, in Mr. Blenkinsop's opinion, it had been open to the Government to withdraw the charges, instead of making extra revenue available to those who were already well off. Mr. Blenkinsop deplored the maintenance of the financial ceiling for the health service. The Minister had said with pride that the hospital authorities had saved large sums from their estimates last year, but many knew that these savings had been made at the cost of the proper running of the service.

Mr. **Frederick Messer** accepted the need for an investigation into the organisation of the N.H.S., but asked that the emphasis should be on efficiency rather than economy. In a comprehensive service unification was important, and Mr. Messer pointed out that each of the 14 hospital regions cut through the staff of the local health authorities. We should, he held, investigate the possibility of a rearrangement of the regional-board structure so that the periphery was coterminous with the local authorities—not of course a single local authority, because obviously a regional board must be larger than any single local health authority. He regretted that the service was divided into three sections, and he was anxious that more attention should be given to the preventive side. Would the Minister consider whether the executive councils could not become part of the local health authorities? Not only would this save administrative costs but it would bring the general prctitioner into a closer relationship with the preventive service.

Dr. **Santo Jeger** believed that on the whole people would spend on their health what they needed. In America about 4½% of the national income was spent on health, but 90% of it was spent privately and only about 10% publicly. In this country we spent about 4% of our national income on health; but about 90% of it was spent publicly, and only 10% privately.

Colonel **Malcolm Stoddart-Scott** also felt that the organisation of the executive councils was unsatisfactory. He believed there were too many. Some councils administered their areas at a cost of 10*d*. per head of the population, others at 2*s*. 10*d*. He believed that by cutting the number of councils we could save at least £500,000 a year. He also recommended that the powers of the regional hospital boards should be swept away. On the whole they acted only as post-offices between the hospital management committees and the Minister. They also increased the difference between the standards of the teaching hospitals and the other hospitals. He would like to see the H.M.C.s rise in standard to that of the governors of teaching hospitals and to have increased powers and direct access to the Minister. The regional offices of the Ministry could, he suggested, be strengthened to deal with over-all planning, and he thought that the teaching hospitals should be brought under the Ministry's regional over-all planning.

Mr. **H. A. Marquand** pointed out that the proportion of our national income which was being spent on the N.H.S. was dropping, because the Government had stuck to the £400 million ceiling even though circumstances had changed and the Chancellor had twice been able to reduce taxation. Yet, Mr. Marquand held, there were cogent reasons for raising the ceiling. If we had the steel, for instance, it was false economy to deprive hospitals of fuel-saving appliances. The increase in our population, regurgitation is severe, the symptoms are probably due to mitral stenosis Pulmonary hypertension from aortic regurgitation does not develop until left ventricular failure is manifest, and therefore cardiac catheterisation may be of value in the assessment

When there is difficulty in differentiating an Austin Flint murmur from the mid-diastolic murmur of mitral stenosis, we have found that the presence of an opening snap is conclusive evidence of mitral stenosis

Aortic Stenosis

Aortic stenosis has to be of considerable degree before effects on the circulation are evident The left ventricle hypertrophies but dilates little, and this is reflected in the quality of the apical impulse, in the contour (and, later, the volume) of the left ventricle, and in the electrocardiogram The pulse rate is slow to rise, and the pulse is small and sustained (plateau type) The blood-pressure is low if stenosis is severe, and the pulse-pressure is reduced These features may be modified by the aortic incompetence which often accompanies the stenosis The aortic second sound is often weak or absent The familiar basal systolic murmur and thrill signify sclerosis of the aortic valve but not necessarily stenosis, which must be diagnosed on other grounds

GROSS CARDIAC ENLARGEMENT

It is impossible to lay down absolute standards of size beyond which it is unwise to operate Left atrial enlargement is not related to the degree of stenosis, it is the size of the right ventricle which matters most

Cardiac enlargement in patients with mitral stenosis is related to the effects of rheumatic myocarditis rather than to the valvular defect The benefit which will accrue from relieving the strain on damaged muscle by diminishing mechanical obstruction is obvious, but there must be a stage of cardiac damage, indicated by gross enlargement, beyond which significant benefit cannot be expected and the risk of operation is too great. In short, the degree of cardiac enlargement is only one of the factors which must be taken into consideration in assessing the desirability of operation

ACTIVE CARDIAC DISEASE

Subacute bacterial endocarditis is an obvious contra-indication to operation Except when the mechanical obstruction at the mitral valve is an immediate threat to life, it would seem more reasonable to wait for six months after successful treatment before undertaking valvulotomy, if only to diminish the risk of dislodging emboli Only 2 patients in this series had had such an infection in neither of them was there any untoward incident during or after operation

In the presence of valvular heart disease clinical signs of active rheumatic carditis may be impossible to assess Electrocardiography is not a reliable guide unless there are significant changes in serial records, and is of no value if there is auricular fibrillation Nobody would advise operation for anyone with obvious signs of rheumatic activity in the form of pericarditis, swollen joints, anæmia, or a high erythrocyte sedimentation rate, but there are patients with vague joint pains or a moderately raised erythrocyte sedimentation rate in whom the decision is difficult We have operated on such patients without evidence of postoperative recrudescence There have been others without symptoms of activity before operation who have apparently developed mild rheumatic fever during convalescence There is no evidence that operation necessarily aggravates the rheumatic process, and delay in patients with tight stenosis may carry the greater risk

Preoperative Treatment

Before any deliberate thoracotomy, patients are instructed in breathing exercises by a physiotherapist so that they may be efficient after operation in the expectoration of bronchial mucus and the promotion of full re-expansion of the lungs

Cardiac failure is corrected if possible, but occasionally the operation has had to be done while there were still signs of congestive cardiac failure 3 patients with intractable cardiac failure have been considerably improved by *ligation of the inferior vena cava*; after which, if improvement continues, it may be possible to treat the valvular defect Benefit may accrue mechanically from increasing the vascular bed in the lower half of the body, and the diminution in venous return may improve the cardiac output by lowering the right auricular filling pressure and hence lead to improvement in renal blood-flow

Digitalis is given to patients with auricular fibrillation, and quinidine is given prophylactically to all patients with sinus rhythm

Operation

The main steps of the operation performed in most cases were as follows

Under cyclopropane anæsthesia, with the patient lying on the right side, a standard left thoracotomy was made through either the fifth interspace (in patients under thirty years of age) or the bed of the resected fifth rib (in patients over thirty) The pericardium was opened from apex to base of the heart 1 cm anterior to the phrenic nerve and parallel to it The left auricle was incised to allow digital exploration of the atrium and the mitral valve The anterior and posterior commissures of the valve were divided by pressure with the index finger The auricular and pericardial incisions were repaired, a low intercostal drain was introduced into the pleural space, and the chest was closed During the operation blood was replaced by transfusion according to the weight of blood lost

In 41 cases the lung felt abnormally heavy and solid, and in 34 there was a clear pleural effusion of 20–30 ml The heaviness of the lung bore no constant relation to the size of the mitral orifice or to the preoperative assessment of pulmonary congestion, and was not prognostic of difficulty during convalescence In 80 cases a wedge of tissue was removed, for microscopy, from the anterior segment of the lung—a site chosen in preference to the lingula, which is more often involved in primary pulmonary disease

In most cases there was 10–20 ml of clear pericardial liquid, but in 20 cases the quantity was between 30 and 300 ml In 6 cases the pericardium was completely adherent to the epicardium by dense avascular adhesions

In almost all the cases a diastolic thrill was felt on the surface of the heart immediately to the left of the interventricular branch of the left coronary artery, diminishing in intensity towards the apex of the left ventricle In some the thrill could also be felt on the inferior surface of the left ventricle near the interventricular artery A systolic thrill below the left lower pulmonary vein, maximal on the auricular side of the coronary sulcus but also present on its ventricular side, was felt in 14 cases out of 22 in which mitral regurgitation was found at cardiotomy A similar thrill was felt in 4 cases out of 9 in which mild regurgitation was produced by valvulotomy In 3 cases a systolic or systolic and diastolic thrill was felt at the origin of the aorta, and in these aortic valvular disease had been diagnosed before operation

The occasional disappearance of a systolic or a diastolic left ventricular thrill after valvulotomy was believed to be caused rather by the less forceful action of the heart than by the correction of incompetence or by the relief of obstruction

In the earlier days of mitral surgery the fragility of the distended left atrium was an argument against the use of the atrial approach to the valve It is now known, however, that the atrial wall holds sutures well, even against high pressures The auricle is normally broad enough to accommodate the index finger, and, when that with its higher proportion of aged and young people, was another reason for spending more on the N.H.S. Again, much of our hospital equipment was obsolescent, and finally the needs of the new towns and housing estates must be considered. He hoped that the Minister would ask the Guillebaud Committee to consider how the service could be run more economically by providing better capital equipment, and whether it might not be sensible to present the capital account of the health service separately from the current account. Mr. Marquand said that the Trades Union Congress, before appointing a representative to the Guillebaud Committee, had questioned the terms of reference, as they had thought the words "to avoid a rising charge" implied that the committee must keep within a ceiling. The T.U.C. had been given a "clarification," and the Chancellor of the Exchequer had given an assurance that the committee had been given no ceiling. Mr. Marquand asked for a definite assurance that the committee would be free to recommend changes which would involve increased expenditure.

GOVERNMENT REPLY AND DIVISION

Commander T. D. GALBRAITH, Under-Secretary of State, Scottish Office, replying to the debate, said the Guillebaud Committee would be able to study the merits of whole-time and part-time service, but it would not deal with rates of pay. He was sure that the committee would arrange sittings in Scotland and hear Scottish evidence.

Mr. BEVAN moved to reduce the token vote for the National Health Service for the current year by £5. The motion was negatived by 293 votes to 268: Government majority 25.

Hospital Nursing Services

In the House of Lords on May 12, Lord CROOK said that he noted with concern that today there were employed in the hospitals 47,000 fully trained nurses and some 8000 part-time nurses as against 52,000 trained nurses and another 48,000 in training in 1948. Present employment could not meet the needs of the present situation, much less the potential growth of the health service. He had chosen this moment to raise the subject, he explained, because the report of the Nuffield Provincial Trust made it plain that the most skilled nurses were not being used in the most skilful jobs. The report made it clear that proper use was not being made of ward orderlies, though 25,000 members of that grade were now employed. Almost three-quarters of the time spent on nursing duties in the wards was contributed by student nurses, and only 16% of the time spent on nursing duties was given by trained nurses. The staff nurse had only a small amount of time to devote to actual nursing. The time spent in training the student nurses was negligible, ranging from eleven hours a week to seven minutes. One of the deterrents to the recruitment of nurses had been domestic work, and Lord Crook was glad that the amount of domestic work performed by student nurses was today much lower. Instead, the worrying thing was the nature of the nursing duties allocated to them. Everyone was accustomed to student nurses taking pulses and temperatures, but the report showed that, apart from doing dressings, student nurses now gave injections, were responsible for checking drugs, and carried out urine tests. Indeed, 72% of the total time spent on the dressings of patients was contributed by student nurses. Yet the theory of wound dressing was, in the main, shown to be picked up rather than taught. Much of the waste of man-power, Lord Crook continued, was due to the poor design of buildings and the shortage of good equipment. There should be some system of priorities to make certain that money was spent on equipment that would ease the man-power problem. The report revealed shortages of elementary hospital equipment which ought not to exist in a State health service, and the Central Health Services Council had said that they saw no reason why financial stringency should prevent the provision of, for instance, adequate facilities for the sterilisation of bedpans.

The number of under-staffed hospital beds in April this year was 28,502, and the present shortage of nurses was estimated to be 10,420. In the last four and a half years the improvement had been very slow, and Lord Crook hoped that the House would be given an assurance about the 5% reduction in staffs which he understood the Ministry had told hospital management committees to make. If the cut was applied to domestic staff, domestic work would again fall on the student nurses who would flow out of the hospitals even faster than they were doing so now.

Lord MORAN said that since three-quarters of the patients in hospitals were nursed by student nurses, it was important that these students should have the benefit of instruction and supervision by trained nurses. The scarcity of nurses was not a passing factor. As the wastage of student nurses in training was 50%, no great increase in the number of trained nurses could be looked for in the future. We must concentrate on making the best use of those we had. For instance, he asked, were there any activities of the nurse which could be done by somebody who was not a nurse? He wondered whether some nursing procedures were not apt to degenerate into rituals. Was it necessary to take the pulse, respiration, and temperature of a patient up to the moment he walked out as a convalescent? One hour of the sister's nine-hour day was devoted to clerical work and nearly all of it could be done by a secretary. Yet when an enterprising provincial hospital instituted the secretarial system they were told to desist on the grounds of economy. Another hour was given up to going round with doctors. In the male ward surely much of that was unnecessary. At the risk of offending many of his own profession, Lord Moran suggested that no doctor should go round a ward before 10 A.M. or between noon and 2 P.M., or after 5 P.M. There must be more coöperation with nurses if they were to economise their time.

The question whether any of the nurse's activities could be done by a nurse who was not necessarily a trained nurse was, he admitted, more controversial. The theme of the job analysis described in the Nuffield report was that the trained nurse had been taken away from the bedside and that she ought to be brought back to the patient. He agreed that the nurse must learn the art of accurate and discriminating observation at the bedside. Only the repetition of apparently menial duties allowed the nurse to get to know her patient. On the other hand it was said that all, or most, of these bedside duties could be done by a person not as skilled as a trained nurse, and at a time of great scarcity of trained nurses it logically followed that less skilled persons should be provided for the work. Nobody had ever introduced dilution into a trade or profession without profound controversy, but, he pointed out, dilution had taken place among almoners; among dentists it was being considered; and the doctor had already been diluted. After all, the nurse was dilution. She was now doing jobs which the doctor did years ago. It was inevitable that there should be dilution in the nursing profession. Those who spoke for the nursing and medical professions were generally attached to teaching hospitals, yet half the hospital beds in this country were in mental hospitals. Surely the case for dilution of the nursing profession was overwhelming. If the diluting agent could be the assistant nurse everyone would be happy, but there did not appear to [illegible] of getting [illegible]ly. anything like enough of them. [illegible] He felt that orderlies trained for a year would be most useful, at any rate in hospitals where acute cases were not treated.

We could not leave aside redistribution when considering the best use of the trained nurse. In sanatoria, in mental hospitals, and in institutions for the chronic sick and elderly, there was probably a gross shortage of trained nurses. But if a nurse was to be sent to these institutions, Lord Moran believed that she must go voluntarily—there could be no direction of labour. He also felt that, at a time when nurses were so scarce, it was surely wise to be very prudent before further depleting the hospitals where acute illness was nursed.

Lord AMULREE agreed that some form of dilution was the only way round our difficulties. One of the ways in which dilution could be introduced without serious harm was by making different arrangements, so that nurses could care for more people than they did now.

is so, exploration of the mitral valve through an incision in the auricle presents no difficulty—the incision being controlled with a purse-string suture or light clamp. In a man aged fifty-three valvulotomy for mitral stenosis was intended, but the auricle proved to be a mere muscular nodule without a lumen. Valvulotomy was therefore not done, and the patient died six months later from acute pulmonary œdema. In 3 similar cases seen later it was found convenient to open the atrial wall in a line from the tip of the auricle to the front of the left upper pulmonary vein. By gentle traction on the auricle and vein the atrial wall in that line can be raised to form a ridge below which a light curved clamp can be applied. In 4 other cases, in which the upper pulmonary vein was capacious, an incision confined to the anterior wall of the vein was used, the vein being controlled at its pulmonary end with a double loop of silk and at its atrial end with a clamp. This venous incision gains advantage from the facts that, when the atrium contains clot, the part related to the pulmonary venous orifice is likeliest to be free from clot, and that, when the atrial wall is sclerosed or calcified, the vein does not share in this rigidity.

From observations during pulmonary resection it is clear that an atrial incision near the termination of the two left pulmonary veins would be simple to control, but the occasion to use this approach has not arisen.

In some cases the auricle, though not atrophic, has a lumen not quite wide enough for the index finger, and exploration through an auricular incision will cause an atrial tear which may be difficult to control either because of its relation to the left coronary artery or merely because it is not readily accessible. It is better to make an adequate incision in a line of easy control than to risk an accidental tear in an incorrect position.

To permit histological examination of the heart muscle the tip of the auricle was cut off before closure of the auricular incision. This series of specimens is still being studied. The finding of Aschoff nodes and other evidence of rheumatic infection does not correspond closely to the clinical evidence of active rheumatic carditis.

The incision, whether in auricle, atrium, or vein, was closed with a continuous 00 silk suture.

BEHAVIOUR OF HEART AT VALVULOTOMY

Extrasystoles occurred in almost all the cases during the earlier manipulations of the heart. In this series intravenous 1% procaine 0.5–4.5 g was given in all the cases, but extrasystoles were quite as common as in the series treated in another hospital in which procaine was not given. Neither procaine nor amethocaine was applied to the pericardium or epicardium or injected into the myocardium, but care was taken to preserve the surface of the heart from unnecessary damage, and especially from drying. Extrasystoles were not produced by touching any of the accessible parts of the interior of the heart. While the finger lay in the stenosed valve, the ventricular action rapidly diminished in force and rate but in most cases quickly returned almost to its earlier state on withdrawal of the finger. In some the beat continued to be slow and weak or even to deteriorate after completion of valvulotomy, and in these the intravenous injection of 'Methedrine' 5–20 mg was usually followed by an increase, first in the vigour, and later in the rate, of the beat.

The reason for progressive slowing of the heart is unknown. Anoxia does not appear to be the cause. It is not clearly related to cyclopropane anæsthesia. In a few cases the deterioration progressed until the heart stopped. Its action, except in 1 case in which the ventricle began to fibrillate, returned after cardiac massage.

Ventricular fibrillation was observed in 3 cases, 1 of them fatal, in this series and in 1 case in the series in which intravenous procaine was not given.

Sudden improvement of the heart's action after valvulotomy is rarely to be expected, probably because enough blood passes easily through the stenosed orifice for basal requirements. The benefit from valvulotomy can be appreciated only when greater demands are made on the circulation.

EXPLORATION OF ATRIUM

The absence of palpable movement of the atrial blood was a striking feature in most cases. The uncovered finger was not used, and the sensitivity of the gloved finger to the flow of blood is not comparable with its sensitivity to minute hard bodies. With the finger close to the orifice of a pulmonary vein through which a quarter of the whole circulation is flowing no current is appreciated. There is no sensation of turbulence above the mitral valve. In nearly all the cases the medial (anterior) cusp bulged with a sharp impulse into the atrium at each ventricular systole. In the exceptions the whole cusp was apparently rendered rigid by disease.

In 26 of the 100 cases of predominant stenosis regurgitation of blood from the ventricle was felt before valvulotomy. In none of these was regurgitation abolished by valvulotomy. It was thought that in some it had been reduced, but the impairment of the heart's action which sometimes occurs during valvulotomy may have been responsible for diminution of the leak. In addition the enlarged orifice alters the character of the flow, and comparison of a broad soft current with a narrow hard jet is inaccurate. In 7 cases there was slight regurgitation after valvulotomy when none had been felt before. The lightest touch on the anterior cusp either before or after valvulotomy, if the cusp was mobile, led to the regurgitation of blood into the atrium.

Three grades of size of the mitral orifice were recorded. In group 1 the valve would admit no more than the tip of the index finger. By comparison with post-mortem specimens this was judged to be in most cases about 1 × 0.5 cm. Group 2 ranged from admission of the extreme tip to admission of the whole terminal phalanx. In group 3 the second phalanx or more was admitted. In the combined series of 130 cases there were 17 in group 3, the orifice loosely admitting the first knuckle of the index finger. They are referred to here only to illustrate points in diagnosis. At present we do not know precisely what degree of stenosis and what degree of regurgitation are of dynamic significance. Variables such as auricular fibrillation, myocardial damage, mobility of the cusps, atrial size, pulmonary hypertension and pulmonary vascular resistance may always prevent precision. We consider that a broad regurgitant jet through a valve which admits the proximal interphalangeal joint of the index finger signifies predominant mitral incompetence, and in our experience no reduction in the regurgitation can be expected after division of the commissures. A faint regurgitant jet through a tightly stenosed valve is not of dynamic significance. When the mitral orifice just admits the terminal phalanx of the index finger, the degree of stenosis is significant, and there may or may not be also significant regurgitation. In cases with regurgitation through an orifice admitting the terminal phalanx no appreciable reduction of regurgitation has been achieved by valvulotomy, although the patients have been improved.

EMBOLISM

Embolism is the greatest immediate danger associated with valvulotomy. It must be weighed against the possibility of embolism without operation, and of progressive ill health from unrelieved mitral stenosis. The finding of clot in the auricle or atrium is unpredictable. It is more common in those who have auricular fibrillation or have had previous embolic incidents than in those with normal rhythm and without previous embolism. If

A MODIFIED SCHLESINGER TEST FOR UROBILIN IN URINE

H. F. W. Kirkpatrick
Ph.D. Lond., F.R.I.C.
CHEMICAL PATHOLOGIST, DEPARTMENT OF CLINICAL INVESTIGATION, THE LONDON CLINIC

The testing of urine for urobilinogen and urobilin is of special importance in the early diagnosis of hepatitis, in following the course of the disease, and, by its final disappearance, in denoting complete recovery. The significance of the test is emphasised in a comprehensive review of liver-function tests by Gray (1950).

Ehrlich's test for urobilinogen must be made on freshly voided urine because urobilinogen is readily oxidised to urobilin on exposure to air. As immediate testing of urine is not always practicable, the test for urobilin thus has an obvious advantage. Schlesinger's test as usually performed, however, is relatively insensitive to small increases in urobilin. A modified procedure, which has been in use in this laboratory during the past two years, has proved very much more sensitive in detecting any increase in urobilin.

Principle.—The modification consists essentially in extracting the zinc-urobilin complex with chloroform and examining the chloroform solution in filtered ultraviolet light for a characteristic golden-yellow fluorescence. The best technique was decided by preliminary experiments as a result of which the following points were noted:

(1) Filtration before extraction with chloroform removes up to 40% of the fluorescence and must therefore be avoided.

(2) Addition of acid or alkali to the urine is unnecessary and undesirable. The zinc-urobilin is especially sensitive to acid.

(3) The use of iodine as oxidant in converting urobilinogen to urobilin is unsatisfactory because excess of iodine interferes with the production and extraction of the complex. This difficulty is avoided by the use of ammonium persulphate.

(4) Extraction with chloroform by gentle shaking for about 10 sec. removes 90–100% of the zinc-urobilin without any complicating emulsion.

(5) The test may be made on any convenient volume of urine (as little as 2 ml. if desired) by using proportional volumes of the other reagents.

Method.—To 5 ml. of urine in a small separator add a few crystals of ammonium persulphate and shake to dissolve. Add 5 ml. of saturated alcoholic zinc acetate and mix. Add 10 ml. of chloroform, shake gently, allow to separate, and run off the chloroform layer into a test-tube. Add a few drops of absolute alcohol to clarify, mix and examine in filtered ultraviolet light.

Interpretation.—The observation of a golden-yellow fluorescence is a positive indication of the presence of urobilin. A gross or moderate increase in urobilin is unmistakable, but greater certainty in detecting slight increases can be obtained by dividing the chloroform into equal parts, adding a crystal of trichloracetic acid to one to destroy any zinc-urobilin complex present, and comparing the fluorescence of the two portions side by side, when any definite yellow fluorescence in the untreated portion becomes easily discernible. A white or blue fluorescence is regarded as negative. Normal urine yields a bluish-white fluorescence which may occasionally have a slight yellow tinge, but a distinct yellow fluorescence may always be regarded as indicating increased excretion of urobilin. The test may be applied to fresh urine or to urine which is several days old with equally reliable results.

If a fluorimeter is available, the test may be made roughly quantitative by measuring the fluorescence with a primary Wood's screen and a secondary yellow or orange screen, before and after addition of a crystal of trichloracetic acid, the latter reading providing the blank, and comparing with a standard sodium-fluorescein solution (0·1% diluted 1 to 1000 or 1 to 2000).

The qualitative effect of bilirubin is to impart a yellowish colour to the chloroform solution but shows no fluorescence. Quantitatively, bilirubin interferes with the fluorimeter reading by absorbing the ultraviolet light used for activating the fluorescence. This effect can be largely overcome by diluting the chloroform solution stepwise until successive readings show a linear relation between reading and dilution.

CORTISONE AND LIVER FUNCTION

K. Aterman

RESEARCH FELLOW, DEPARTMENT OF PHARMACOLOGY

THE MEDICAL SCHOOL, UNIVERSITY OF BIRMINGHAM

Since the amount of fibrous tissue deposited in the liver of rats given carbon tetrachloride is reduced if cortisone is administered simultaneously (Aterman 1950, 1952, Cavallero et al. 1951), it is of interest to discover whether this neutralising effect is associated with a corresponding change in the function of the liver. Drill and Ivy (1944), who studied various liver-function tests in dogs receiving carbon tetrachloride, regarded the 'Bromsulphalein' retention test as one of the most sensitive indices of liver damage. After the adaptation of this test to small animals, and the demonstration of its suitability for assessing the degree of liver damage in the experimental fibrosis of carbon-tetrachloride poisoning in rats (Ahmad and Frazer 1952), it was chosen for a study of the effect of cortisone on the liver function of such rats.

METHOD

23 male albino rats of an inbred strain used in this laboratory, weighing 150–206 g. (average 177 g.) and fed on the stock laboratory rat cake diet ad lib., were given twenty-one subcutaneous injections of 0·2 ml. of carbon tetrachloride in seven and a half weeks at intervals of two or three days. After the seventeenth injection food, but not water, was withdrawn for sixteen hours, and next morning the bromsulphalein test was made by the method of Ahmad and Frazer (1952). Next day treatment with cortisone was started in a group of 12 rats, the remainder being kept as controls. Cortisone acetate ('Cortone' Merck) was given intramuscularly in two divided doses, the daily dose being 12·5 mg. on the first and last day, and 10 mg. and 8·75 mg. alternately for the rest of the experiment, with a day's interval in which no cortisone was given. Each rat therefore received 90 mg. of cortisone in ten days. Throughout this period the injections of carbon tetrachloride were continued in both groups. After the twenty-first injection, which coincided with the last day of the treatment with cortisone, all the rats were again starved for sixteen hours, and next day the bromsulphalein test was repeated. The rats were then killed, pieces of their livers were fixed in 5% formol-saline solution, and 7μ sections of liver were stained with hæmatoxylin and eosin and with the Mallory-Azan stain.

Another group of 5 male rats, weighing 200–240 g. (average 215 g.), was given cortisone alone in the same dosage as the previous group. Since the bromsulphalein retention of normal rats had been found to be fairly constant (Ahmad and Frazer 1952), the first test, before the start of the treatment with cortisone, was omitted, and the bromsulphalein retention was determined in this group only at the end of the experiment.

It should be emphasised that, in the calculation of the amount of bromsulphalein to be given, the considerable loss of weight caused by cortisone was taken into account The standard dose of bromsulphalein in each case was 25 mg per kg of body-weight

RESULTS

Table I shows the results of the experiment Judged by the amount of bromsulphalein retention at the time of the first test, the carbon tetrachloride had produced different degrees of liver damage This variation in susceptibility is a well-known feature of *carbon-tetrachloride* poisoning in rats But, whereas the continuation of the injections of carbon tetrachloride in the controls led to only minor changes of liver function during the ten days' interval between the first and the second *bromsulphalein tests, the simultaneous administration* of cortisone to the other group produced a striking deterioration in the elimination of bromsulphalein *in practically* every rat Improvement was shown by only 1 rat The degree of deterioration did not seem to be related to the loss of weight sustained In contrast to this group, however, the control rats, receiving cortisone only, showed no conspicuous change in the rate of elimination of bromsulphalein (table II)

Standard dose of bromsulphalein 25 mg per kg of body weight intravenously
10 mg per 100 ml of serum = 100 % retention
Normal value = 2 91 % ±0 052

The histological examination of the liver sections tended to bear out these results Since cortisone lessens the amount of fibrous tissue in early fibrosis, it is not surprising that in all but one animal (table I, no 5), the fibrosis was mild or absent The main interest attaches to the changes in the liver cells The cytological effects of the subcutaneous administration of small doses of carbon tetrachloride have been described by several workers (Cameron and Karunaratne 1936, Brunschwig et al 1945, Glynn and Himsworth 1946, Himsworth 1947) They consist, briefly, of fatty vacuolation eosinophilic staining of the cytoplasm with or withou pyknosis of the nucleus, and a peculiar "ballooning" o "hydropic degeneration" of some of the liver cells A characteristic feature of this picture is the zonal, pre dominantly centrilobular, distribution of these cellula changes Although the extent of the lesions may vary, a a rule there is, in the absence of advanced fibros sufficient intact parenchyma left, particularly in th periportal region, *to explain the degree of bromsulphalei* clearance found in this group (fig 1)

TABLE II—EFFECT OF CORTISONE ON BROMSULPHALEIN EXCRETION IN NORMAL RATS

Second test* (after treatment with cortisone)			
Rat no	Body weight (g)	Loss of weight (g)	B S P retention (%)
25	160	40	2 12
26	162	44	2 12
27	165	44	1 91
28	186	54	1 91
29	160	54	2 12

*Normal value = 2 91 % ±0 52

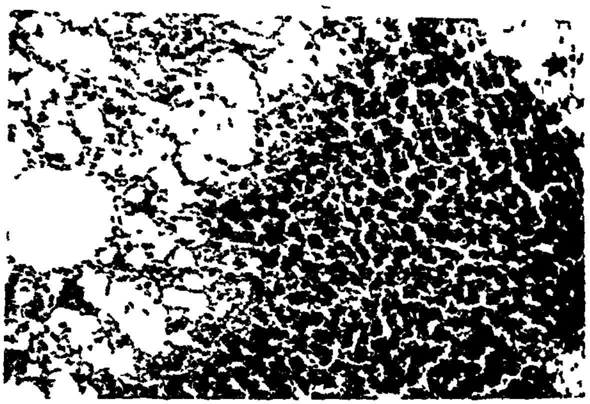

Fig 1—Rat no 23 (twenty-one injections of carbon tetrachloride) characteristic localisation of "ballooning" round central hepatic vein Note amount of histologically intact liver parenchyma. (5% formol saline solution Hæmatoxylin and eosin × 100)

The histological picture is changed in the rats receivin both carbon tetrachloride and cortisone The charac teristic zonal distribution of the cellular degenerativ changes is obliterated to various degrees, instead, th impression of a mosaic (figs 2 and 3) is gained, see particularly well in sections stained with Mallory Azan *The* dominant *feature now is an apparently haphazard* distribution of cells which vary greatly in their staining reactions and present more vacuolation as well as various transition forms to the "balloon like" cells The number of the latter is possibly also increased, whereas the number of histologically intact cells is distinctly reduced The whole picture now is one of rather severe damage Within broad limits it was possible to correlate the impairment of liver function with the histological picture Rat no 2 (table I), for instance, showed the least histological damage, whereas rat no 5 (table I), with severe functional impairment, *not only showed* the most

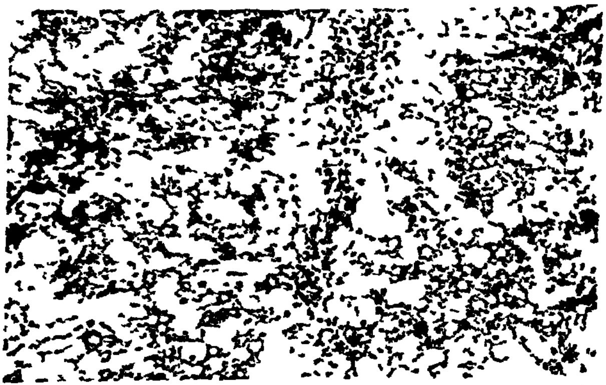

Fig 2—Rat no 5 (twenty-one injections of carbon tetrachloride, cortisone 90 mg in ten days) mosaic of cells with more vacuoles and unequal staining reaction (5% formol saline solution Hæmatoxylin and eosin × 100)

clot is found, the chance of its dislodgment is considerable, but, in view of the alternative dangers, is not so great as to force the abandonment of valvulotomy in a patient already judged to require it. In the first 44 of this series clot was found in 4 and embolism occurred in all. In 1 it was a fatal cerebral embolism. From that time precautions have been taken against embolism, first in patients with auricular fibrillation or known to have suffered embolism, and later in all cases. In the 66 cases, since precautions have been taken, clot has been found in 15 and embolism has occurred in 2. In addition, 1 patient developed embolism two months later, and another, with a past history of embolism, ten days after operation.

During all manipulations of the auricle and atrium, until it is reasonably certain that no clot remains in them, both common carotid arteries are compressed in the neck. It has not been considered necessary to expose the arteries of the neck provided that they are palpated with certainty and compressed. Before the auricle is clamped or sutured, an incision is made near its tip, and 3–5 oz. of blood is allowed to gush out so that loose clot may be carried with it. If the flow is not free, or fragments of clot are seen in the escaped blood, this lavage is repeated. If clot is felt within the atrium, lavage is repeated after exploration of the atrium and before valvulotomy. By this means all loose clot is removed before the valvular orifice is enlarged. This is the essential part of the procedure, and its success remains surprising.

The numbers are too small to show whether carotid compression is of value. The value of this manœuvre is uncertain, because in this series no patient whose carotid arteries were compressed during operation developed systemic embolism in any branch of the aorta beyond the carotids. We have some reason to suspect that the procedure may be dangerous because of the risk of cerebral anoxia; and, until the experience of other observers using a similar technique is known, we have decided to give it up.

Besides apparently loose clot, which has varied in quantity from minute fragments in the auricle to a mass filling a large part of the atrium and requiring ring forceps for its removal, two other types of clot have been observed:

(1) A layer of tough, largely organised, and widely attached clot lying on the wall of either auricle or atrium; (2) An organised clot attached by a pedicle to the auricular or atrial wall and with unorganised clot on its surface.

If a wide plaque of clot is found it is disturbed as little as possible. Part of it may need to be separated from the atrial wall to allow access to the valve, or the finger may be passed through the layer of clot. There appears to be little danger from this kind of clot, provided that its removal is not attempted. The second type, apart from small polyps in the auricle, has been seen on only one occasion:

A pedicled sphere, 3 cm. in diameter, was felt within the atrium. The attempt to remove it through the auricle was unsuccessful. It felt like a tumour, but the fragments removed consisted of organised clot. The main mass was left in the atrium, and no ill effect has arisen from it in the fifteen months since operation. The danger that it may enlarge and cause symptoms in virtue of its position or by the detachment of fragments is great enough to have justified a more sustained attempt at its removal before valvulotomy. The pedicle was on the posterior atrial wall within easy reach of the exploring finger. A 3 cm. incision on the posterior atrial wall close to the pedicle and large enough for delivery of the mass could probably have been safely closed.

In the series of 100, clot was found in 20 cases. In 1 case the rhythm was normal and in 18 that of auricular fibrillation. In 9 there was a history of systemic embolism. In 6 induration of the atrial wall was appreciated before the auricle was opened.

VALVULOTOMY

Valvulotomy was in all cases performed by digital pressure on the commissures. In some cases instrumental division of the commissures would have improved the orifice, but a knife was not successfully used. In the earlier part of the series efforts at division of the commissures were readily given up when the orifice would loosely accommodate the first knuckle of the index finger, and complete division of a commissure, which was later recognised as having occurred in a few cases, was accidental. It is possible that in no case in the series was the posterior commissure completely divided, but in most of the later cases the anterior commissure was completely divided. Until the finger has passed through the orifice and can feel the cusps from the ventricular side, the fact that the orifice is at the ventricular end of a funnel is not readily appreciated. The orifice from above feels like a hole in a diaphragm, and the commissures curve away from the posterior cusp anteriorly and posteriorly. The site of the commissures becomes clear by their division. Complete division of the anterior commissure has an unmistakable termination, but to achieve it without the help of a knife both persistence and a fair amount of force may be required.

In some cases the cusps felt almost normal and were held together by adhesions so fragile that valvulotomy was accomplished almost during the estimation of the size of the valve gap; yet in these cases with only slight valvular damage the symptoms of stenosis were severe. Two main obstacles to satisfactory valvulotomy were diffuse rubbery toughness of the commissures, for which a knife was probably necessary but not used, and massive sclerosis at the commissures, by which the valve ring, ventricular wall, and cusps were fused in one tough lump, whose division, even if it had been possible, held no prospect of benefit. Resilient sclerosis was encountered on 8 occasions, and massive sclerosis at the commissures on 5. In a few cases a mass of fused chordæ tendineæ was felt below the divided mitral commissures, and since it appeared to contribute to the stenosis its division was attempted. Whereas it required no special skill to divide the commissures in the correct line, the site of division of this mass of chordæ was erratic, and in 1 case its division was followed by rupture of chordæ and some degree of valvular incompetence.

Calcification of the cusps was recorded in 27 cases, in which rough calcified nodules, apparently uncovered by endothelium, were felt on the surface of the cusps. In 7 cases the calcification was extensive; the margins of the valvular orifice seemed to be entirely calcareous, and after valvulotomy calcareous spicules were felt crossing the space resulting from division of the commissures. Calcification did not usually prove an obstacle to division of the commissures, but in 1 case, in which calcification was mainly in the anterior commissure, the line of division of the commissure passed medial to the calcified area, and valvulotomy was followed by some regurgitation.

Deaths from Operation

The risk carried by the operation cannot be assessed on the statistical analysis of a series of cases. The risk for an otherwise healthy adult, under forty years of age, with uncomplicated mitral stenosis must be very slight. Apart from 1 instance of incompatible blood-transfusion no such patient has died in this series. The risk must increase with age, severity of cardiac failure, size of heart, auricular fibrillation, past history of embolic incidents, and concomitant disease in the lungs or elsewhere.

In this series 7 patients died as a direct result of the operation:

(1) A woman of 52, with a severe disability, long-standing auricular fibrillation, and a history of cerebral embolism, died of cerebral embolism which followed displacement of clot from the left atrium by the exploring finger. This death took place

TABLE I

School	No on school register	No of consents obtained	No completing 9 diagnostic swabs	No completing all tests
A	126	116 (92%)	84 (67%)	51 (40%)
B infants	176	139 (79%)	104 (59%)	50 (28%)
B juniors	249	195 (78%)	135 (54%)	73 (29%)
Total	551	450 (82%)	323 (59%)	174 (32%)

The figures in parentheses are percentages of children on the school register

Various workers have reported that diphenan will rid children of oxyurids, and it has been claimed to be non-toxic and tasteless, and to have the advantage of being a vermicide as opposed to a vermifuge (Brann 1922, Disque 1921, Kuitunen-Ekbaum and James 1950, Kjerrulf 1921 Koslowsky 1920, Kretschmer 1920, Schuckhardt 1920, Schule 1920, Selter 1921)

METHODS

Sampling

In the present series all the parents of children attending two county schools, each serving semi-urban districts, were invited to submit their children for examination, and treatment if necessary There were relatively few refusals or "no replies"

In only one or two isolated cases was a child withdrawn by a parent during the survey The school absentee-rate in each school approximated throughout to normal school experience, and it is therefore suggested that the percentage of consents obtained is probably a more valid measure of the sample examined than is the percentage of children who completed all the tests

The planned course, in its entirety, consisted of nine successive daily diagnostic swabs, followed, when any of these were positive, by 10 days' treatment and a further nine post-treatment swabs This necessity for an unbroken attendance for 30 school days was a stringent requirement, nevertheless we have included in this report only those children who satisfied it (table I)

Diagnostic Criteria

The 'Cellophane'-tape technique described by Graham (1941) and Watson and Mac Keith (1946) was used throughout Impressions were taken by applying the cellophane with a wooden applicator to the skin in the anal region The strip of cellophane was then immediately stuck on an ordinary microscope slide The slides were examined unstained under a low-power objective, when the ova were easily seen

No fixed time was laid down for the examination of a slide before classifying it as negative, but on the average 20 slides an hour were examined Some of these hardly required more than a glance owing to the large numbers of ova present No attempt was made to count the ova, but each slide was arbitrarily classified into one of three groups according to the relative number of ova present in the fields examined (No subsequent use was made of this classification)

It is known that the proportion of children found infested increases with the number of impressions taken, up to about 13 (R Mac Keith, personal communication)

The disorganisation of school life occasioned by this survey and the extra work placed on the laboratory were considerable, so we decided on a diagnostic standard of nine daily impressions as being the maximum expedient in the circumstances Even so some 7000 slides were examined

TABLE II—ANALYSIS OF TREATMENT

School	Age (yr)	Dosage (g t.d.s)	Treatment (days)	Manufacturers recommended dosage
A	5–10 –	0 5	10	For children aged 1½–10 yr 0 25 g t.d.s for 7 days followed by repeat course after 7-day interval
B infants	3– 7	0 75	10	
B juniors	6 +–10 –	1 0	10	

Treatment

Diphenan tablets were given thrice daily at the school under supervision for 10 successive days No untoward symptoms were reported, and the children took the tablets willingly Details are given in table II

The circumstances of the survey made it impossible for a second controlled course of treatment to be given as recommended by the manufacturers

Diphenan is said to act by causing extreme muscular contraction of the worm with death within a few moments of contact If diphenan were as effective as has been claimed, both adult and gravid worms would be destroyed, and therefore post-treatment examination should give negative results, at least for a time

RESULTS

The results are tabulated in table III, which shows that of the 174 "positive" children 20% were "cured," 44% were improved in the sense that they gave fewer positive swabs after treatment than before, 18% were worse, and 18% gave the same number of positives before and after treatment

It will be seen that complete cures, judged by the absence of positive post-treatment swabs, were few, most of these 35 children had been lightly infested, 31 of them having given one, two, or three positive swabs out of the nine taken for diagnosis

TABLE III—ANALYSIS OF RESULTS

School	No of children completing course	No giving all negative swabs after treatment	No giving fewer positive swabs after treatment	No giving same no of positives after treatment	No giving increased no of positives after treatment
A	51	6	26	12	7
B infants	50	6	20	13	11
B juniors	73	23	31	6	13
Total	174	35 (20%)	77 (44%)	31 (18%)	31 (18%)

Only in the juniors of school B was treatment given to children who had given nine diagnostic negatives, and of these 15 children only 6 remained negative Of the remainder 6 gave one positive, 2 gave two, and 1 gave three positive post-treatment swabs The results were also analysed for each year of age, but the findings were not significantly different from those given above for the group as a whole

Although the crude figures (table III) indicate that 64% were cured or improved, detailed study of the results of the pre treatment and post-treatment examinations showed that the shift in the direction of improvement was relatively slight, and this could be explained by the tendency towards extra cleanliness during the survey, irrespective of the treatment

The results are even more disappointing when it is realised that the dosage given was at all times considerably in excess of that recommended

Oxyuric infestation is undoubtedly widespread, at least among school children (Jones et al. 1939, Mac Keith and Watson 1948, Coutelen 1950) and our findings suggest an incidence of about 80% The degree of infestation varies in each child from time to time, and seldom are there symptoms indubitably attributable to this parasite

There are many inherent difficulties in investigating the effect of any given treatment in a condition with such characteristics, and, though the present work may leave much to be desired as regards scientific precision, we offer it as an objective assessment of a widely used remedy early in our experience before we adopted routine precautions against systemic embolism.

(2) A man of 42, with severe pulmonary hypertension died as a result of a technical error. Blood which had been prepared for another patient was transfused and proved highly incompatible. After three days' anuria the patient died from tubular necrosis of the kidneys.

(3) A woman of 42, with auricular fibrillation, severe chronic congestive failure, and cardiac cirrhosis of the liver was accepted for valvulotomy because of her otherwise hopeless outlook. She had been bedridden for three years. The valvulotomy was satisfactory, although the cusps were heavily calcified. Her subsequent cardiac condition gave no cause for concern, but two days later she suddenly had an epileptic fit and died. Necropsy did not reveal a satisfactory cause.

(4) A woman of 57, with a severe progressive disability, auricular fibrillation, and high pulmonary hypertension was accepted in spite of her age because there was no other obvious contra-indication to operation. During the thoracotomy the heart-rate became steadily slower, and cardiac massage was given. Simultaneously it was observed that ventricular fibrillation had begun. Massage was continued for half an hour, and various drugs were given but without avail.

(5) A man of 34, with a severe disability, congestive cardiac failure, right ventricular filling pressure 22 mm. Hg, a large heart, electrocardiographic signs of considerable right ventricular hypertrophy, and pulmonary hypertension (mean pressure 75 mm. Hg). The valve was calcified, but the anterior commissures were satisfactorily divided. Two days later the patient suddenly collapsed and died. Necropsy revealed in the left atrium a mass of adherent clot which completely obstructed the mitral orifice. It is believed that this formed shortly before death.

(6) A woman of 38, with intractable cardiac failure, auricular fibrillation, and gross enlargement of the heart, mainly from aneurysmal dilatation of the left atrium, was operated on in the hope that she might obtain sufficient relief to leave her bed and to lead a somewhat more active existence. At operation the anterior commissure of a not very tightly stenosed valve was completely divided. During the closure of the auricle the heart's action stopped, but it was restored by cardiac massage and with methedrine. During the following night her condition deteriorated and the heart again stopped.

(7) A woman of 50, with considerable progressive disability and auricular fibrillation, gave a history of recent systemic embolism. At operation the left atrium was found to contain much clot, loosely pedicled in the auricle. Repeated gushes of blood were required, to wash it out. On coming round from anæsthesia the patient was confused, but there were no localising signs of cerebral embolism. On the fifth postoperative day she suddenly lost consciousness, and she never fully recovered. She developed mesenteric embolism on the tenth day and died forty-eight hours later.

It will be evident that these deaths occurred in patients with severe heart-disease in whom the prognosis without operation was poor. Each gladly accepted the risks of operation because there was a reasonable chance of improvement. Refusal to accept patients in this group would be to deny the chance of a new lease of life to many.

Postoperative Results

Our first patient was a woman of 28 who for some years had been unable to earn her living and was largely confined to the house.

She could walk slowly on the level but was unable to climb stairs. She slept propped up in bed and was subject to attacks of dyspnœa and recurrent hæmoptysis. She had a low fever believed to be related to intense pulmonary congestion and probable patchy infarction. She had signs of mitral stenosis and aortic incompetence. The mean pressure in the pulmonary artery was almost as high as that in the aorta, and electrocardiography confirmed the presence of severe right ventricular hypertrophy (fig. 4a).

At operation tight mitral stenosis was found, and both commissures were partly divided. The orifice, which would not admit the extreme tip of the index finger, was made large enough to accommodate the first knuckle. Convalescence was uninterrupted.

During the next year she trained as a shorthand typist, returned to amateur dramatics, and went for a holiday climbing hills. At Christmas she took an active part in the chorus of a pantomime on the public stage. In the next year she obtained a full-time secretarial post, took charge of a troop of Girl Guides, and was annoyed because she was not accepted for service in the Navy. She ended the year again acting in pantomime, and in addition running the Christmas show at a large factory. She is not aware of undue dyspnœa on exertion and has had no further hæmoptysis. The electrocardiographic signs of ventricular hypertrophy have disappeared (fig. 4b).

Although not all the results are comparable with the first, most of the patients in this series of 100 cases subjected to valvulotomy for predominant mitral stenosis have been much improved. The results of surgical treatment in those with predominant mitral incompetence have been reported separately (Logan and Turner 1952b).

It must be remembered that valvulotomy is not curative. Changes in cusps, chordæ tendineæ, and cardiac muscle persist. The period of follow-up in this series is necessarily short. The best results have been, as might be expected, in those with tight stenosis, normal rhythm, little enlargement of the heart, and no cardiac failure except that associated with paroxysmal dyspnœa. Most of the patients with recurrent hæmoptysis also fared well.

No patient previously subject to attacks of paroxysmal dyspnœa or hæmoptysis (except that due to pulmonary tuberculosis) has had a recurrence.

Those with severe pulmonary hypertension often have secondary changes in the pulmonary arterioles and considerable right ventricular hypertrophy. These changes are at least in part reversible, and striking improvement sometimes takes place.

In 2 cases pulmonary infarction had been so extensive that there was a delay of several months before valvulotomy could be considered even from the point of view of anæsthesia. Both made good postoperative progress.

Age does not preclude improvement even after many years' disablement. Auricular fibrillation presumably indicates myocardial as opposed to valvular damage, and tends to develop in the older patients. Those with auricular fibrillation are usually disabled by dyspnœa on exertion, tiredness, and weakness rather than by paroxysmal dyspnœa and recurrent hæmoptysis; but improvement is often considerable, although the arrhythmia persists and only the mechanical obstruction has been changed.

A patient, aged 42, spontaneously reverted to sinus rhythm three months after valvulotomy, but about six months later fibrillation returned without her being aware of it, and has persisted.

Generally speaking, when the heart is large its muscle is considerably damaged, and great benefit cannot be expected; but, when there is also stenosis and this is reduced by operation, there may be gratifying improvement.

Most patients who are underweight gain about a stone (6 kg.) within a few months of the operation and sometimes within a few weeks.

As already mentioned, some are obviously too ill for operation to be considered; and in others operation is precluded by important complications. But our experience suggests that most patients with predominant mitral stenosis can be safely subjected to valvulotomy in confident expectation of improvement.

Only 7 patients in this series have been followed up for more than two years; 27 have been followed up for one to two years, 26 for six months to a year, and 33 for less than six months. This therefore is necessarily a preliminary report. In 66 out of 74 patients who underwent operation more than three months ago the results could be classified as good or very good. Most patients claim to be very much improved, but it is difficult to classify a result as good if a large heart remains the same size and auricular fibrillation continues—although change in

SUMMARY

An attempt has been made to assess the efficacy of *p*-benzyl-phenyl-carbamate (diphenan) as a vermicide

In 174 school children, aged 3–10 years, in whom infestation with threadworms was demonstrated, diphenan was given far in excess of the normal dosage for ten days

Subsequent examination showed few cures and these mostly in lightly infested children The condition of many was unchanged and that of some worse after treatment

No toxic reactions were encountered

This work would have been quite impossible without the coöperation of the parents and the willing assistance of the school teachers and the school nurse, Miss D Vickers, on whom this work placed a very real burden We also thank Dr C H Jellard and Dr J J Mackintosh and Mr C W Sivell for many hours of tedious work, and gratefully acknowledge the financial assistance and permission to use school facilities given to us by the Norfolk Education Committee and by Dr T Ruddock West, the school medical officer

UNIVERSITY OF MANCHESTER

The following clinical and biochemical observations on patients with acute porphyria in three generations of one family appear to throw some light on the causal effects of porphobilinogen and uroporphyrin

Case 1 —A man, aged 27, had suffered for many years from periodic attacks of hoarseness of voice, paralysis of the arms with wristdrop, and acute abdominal pain accompanied by obstinate constipation He was seen by one of us (F R F), and a diagnosis of acute porphyria was made on clinical grounds and later confirmed by biochemical investigation He was admitted to Manchester Royal Infirmary on March 9, 1942

Progress—For the first three weeks his condition improved considerably, and there was some return of dorsiflexion of the wrists On March 30, however, another attack developed, with intense abdominal pain and vomiting, increasing hoarseness, restlessness, and muscular weakness Nine days later his legs became weak and his voice almost inaudible, and he developed a bilateral facial paresis, but no weakness of tongue or palate Next day he began to have a muttering delirium and occasional muscular spasms which spread from his arms and fingers to his face There was bilateral ptosis, but the pupils reacted to light, and ocular movements seemed full and equal It was impossible to test sensation Pulse and respiration increased in rate though there was no pyrexia during the attack He died on April 11 of respiratory failure

Histology—Dr E Pollak made a comprehensive neurohistological examination and found three processes localised to different parts of the nervous system (1) a very chronic segmented degeneration of myelin sheaths of all peripheral nerves examined (Mason et al 1933), (2) an acute destruction of anterior-horn cells and certain cranial and sympathetic nuclei in the form of a vacuolar degeneration, and (3) a toxic encephalopathic process in the medulla affecting the substantia reticularis

Biochemical Findings (Kench 1943)—48 mg of uroporphyrin III was excreted per litre of urine, mainly as zinc complex Neither uroporphyrin I nor protoporphyrin was detected Urinary coproporphyrin was 163 µg per litre before the attack and 128, 43, and 148 µg per litre during the attack, consisting of approximately equal quantities of isomers I and III Stools contained 0 13 mg of coproporphyrin per 100 g of fresh material during a remission, and 1 81 mg per 100 g during the final attack No uroporphyrin was detected at any time There was an intense positive porphobilinogen reaction in the urine, but the concentration was not measured The liver contained 13 5 mg of coproporphyrin III and 50 µg of protoporphyrin No ether soluble porphyrins were detected fluorimetrically in blood or cerebrospinal fluid, and traces only were found in the spleen

Urine specimens from twelve other members of the patient's family were examined for porphobilinogen and uroporphyrin Except the patient's mother (case 2) all these persons were normal both clinically and biochemically There was no history of consanguineous marriages in the family

Case 2 —The mother, aged 64, had first noticed that her urine was abnormal shortly before the birth of her eldest child (case 1) twenty seven years earlier Her urine was reddish-brown when it was passed but darkened on standing Since that time her urine had been continuously dark, but in spite of this she had never had any of the usual symptoms of porphyria Her only complaint had been of regular attacks of severe prostrating headache and vomiting, which began about the time of onset of the porphyria and resembled migraine (Waldenström 1937)

Biochemical Findings—Studies made in 1943 (Kench 1944) showed uroporphyrin III to be the only porphyrin which could be isolated from the urine, and it was present in concentrations up to 2 mg per litre After experimental *d* glucosamine and liver therapy, however, the excretion of uroporphyrin was greatly increased for twenty eight days, with a maximal value of 27 mg of uroporphyrin per litre Urinary porphobilinogen also showed a peak value at that time, accompanied by an unprecedented attack of headache, vomiting, sleeplessness, and severe constipation of three weeks' duration

Investigation of the urine in November, 1952, has shown the excretion of uroporphyrin and porphobilinogen to be virtually unchanged from values observed in 1943, the porphobilinogen concentration (mean of 7 specimens) being 1 4 Vahlquist units per ml of urine (Vahlquist 1939)

Case 3 —The son of case 1 has been examined at intervals during the last ten years for biochemical or clinical evidence of acute porphyria Now aged 14, he remains in good health, with no clinical signs or symptoms of the disease, but, whereas his urine was quite normal two years ago, it now contains 0 63 Vahlquist units of porphobilinogen per ml The presence of porphobilinogen is characteristic of acute porphyria (Hammond and Welcker 1948) No uroporphyrin could be measured in the urine by the spectrophotometric procedure of Sveinsson et al (1949), either before or after the urine was heated at 100°C at pH 5 2 for thirty minutes (Grieg et al 1950)

These three cases show a grading in clinical severity associated with differences in excretion of porphobilinogen and uroporphyrin as follows

		Biochemical observations	
	Clinical manifestations	*Uroporphyrin*	*Porphobilinogen*
Case 1	+++	+++	+++
Case 2	+	+	+++
Case 3	–	–	+

Porphobilinogen is probably not the causal factor of the characteristic neurological changes in acute porphyria (Rimington 1952), but porphobilinogen and these features is not to be expected. No patient who survived has been made worse.

It will be seen from table II that many results are classed as good, although only partial division of one or both commissures was achieved at operation. An incomplete valvulotomy reducing tight stenosis to moderate stenosis is compatible with great improvement. It is not yet known whether regression will take place, because of either residual stenosis or re-fusion of the cusps.

Apart from the 7 deaths from operation and 1 subsequent death, which are discussed separately, the results were poor in 2 cases:

(1) A woman of 28 had a very large heart and tight stenosis with extensive calcification of the cusps. It had been appreciated that myocardial damage must be severe, but we had hoped that by decreasing the mechanical obstruction material benefit might follow. Although she stood the operation well, the functional result two years later is disappointing although it may be that her life has been prolonged.

(2) A woman of 27 was considerably improved for six months after operation, after which her condition gradually regressed. She was so impressed by the initial result that she volunteered to undergo another operation if the same effect could be achieved. She was observed for a further twelve months, and it became apparent that she was approaching her preoperative state. Accordingly cardiac catheterisation was repeated, and it was found that her pulmonary hypertension (45 mm. Hg at rest) was the same as before operation and rose promptly on exercise. Both mitral commissures had been partially divided, and it seemed either that the cusps had again become adherent or that pulmonary arteriolar resistance was unchanged and a dominant factor in her pulmonary hypertension. Unfortunately at the first investigation her pulmonary capillary venous pressure had not been recorded, but on the second occasion the pulmonary-artery/capillary-venous gradient amounted to 20 mm. Hg, indicating a moderate degree of resistance in the pulmonary arterioles. Since she was young and her symptoms were disabling, a second thoracotomy was done. The extent of recurrent fusion of the cusps was negligible, but it was possible to complete the division of the anterior commissure and increase the division of the posterior. She was again improved, but the second operation took place only three months ago.

The result in 6 patients has been classified as fair: 1 developed a hemiplegia five months later, 2 had very large hearts, 2 are unintelligent, and we doubt that they are as much improved as they maintain, because they did not have much pulmonary hypertension or very tight stenosis, and the valvulotomy was incomplete. In 1 who did not have very tight stenosis but had quite extensive division of the commissures the reason for lack of greater improvement is obscure.

LATER DEATHS

One patient died after returning home*:

A woman of 59 (case 41), with recurring paroxysmal auricular fibrillation which precipitated severe pulmonary œdema, experienced a further attack, with a ventricular rate of 200, a month after returning home. She recovered after intravenous digoxin but ten days later developed hemiplegia from cerebral embolism. Necropsy showed that clot had formed along the line of the auricular incision. Whether this happened during the attack of paroxysmal tachycardia or in the immediate postoperative period was impossible to say. Postoperative convalescence had been smooth, apart from transient symptomless auricular fibrillation.

Assessment of Improvement

Assessment of improvement must be largely subjective, but in most patients the change following valvulotomy leaves the clinician in no doubt that pulmonary congestion has been relieved and the ability of the heart to raise its output on exertion has been increased. Improvement is easiest to assess in those who were previously most disabled. Some patients are convinced that from being grossly disabled they have become normal again.

Dyspnœa is a good guide to deterioration or improvement in patients with mitral stenosis, and reduction of dyspnœa on exertion is the most commonly appreciated effect of valvulotomy. Those who were obliged to sleep propped up in bed may find after operation that they can lie flat without discomfort. Because of the wide variation in the frequency of the attacks prolonged postoperative observation is required before it can be concluded that paroxysmal dyspnœa and hæmoptysis have ceased.

Cough, sputum, and repeated attacks of "bronchitis" are common manifestations of pulmonary congestion and œdema in patients with mitral stenosis, and several patients have remarked on improvement in this respect after valvulotomy.

Vital capacity.—Breathing exercises under the guidance of a physiotherapist were given before and after operation so that a reliable measure of vital capacity might be recorded. There is often some restriction of left diaphragmatic movement after thoracotomy, and it is best to wait three months before attempting to assess improvement by measurement of the vital capacity. In this series the vital capacity has proved a poor guide to the severity of mitral stenosis or to postoperative improvement. The value of more detailed tests of pulmonary function is now being investigated.

Nutrition.—Most patients have gained considerable weight after operation, some of them 7–14 lb. before leaving hospital three or four weeks after operation.

Ability to do more.—Most patients notice an increased feeling of well-being and do things which they were previously unable to do because of lassitude and weakness. A return to household duties and social activities is not the least of the benefits of successful valvulotomy.

Cardiac size.—In most cases there has been no change in the size of the heart other than that resulting from resection of part of the left auricle, but in a few an appreciable reduction has taken place. Preoperative films may show variation in cardiac size according to the position of the diaphragm and the phase of the cardiac cycle in which the exposure was made. This fact makes all but considerable changes in size impossible to estimate.

Electrocardiography.—Regression of signs of right ventricular hypertrophy has been observed in 4 cases. These were all in patients with tight mitral stenosis and severe pulmonary hypertension in whom a wide valvulotomy was achieved.

Psychology.—The psychological effects of the operation have been favourable in every case, but in those relatively little disabled this makes the assessment of organic improvement more difficult.

Pulmonary hypertension and cardiac output.—The measurement of intracardiac pressures and of the cardiac output at rest and on exertion and the calculation of pulmonary resistance are the only objective assessments likely to be of real value. These tests have not so far been repeated after operation in this series. It would be necessary to wait at least a year for improvement to become stabilised. The relationship between accentuation of the pulmonary second sound and pulmonary hypertension is not constant, but intensity is useful as a rough guide and has slowly diminished in most cases.

CHANGE IN CLINICAL SIGNS

The change in clinical signs produced by valvulotomy cannot be predicted from the findings at operation or from the extent of the valvulotomy. In some cases a diminution in signs has resulted, but in most there is little change. Since the sclerotic changes are not affected by the operation, it is perhaps not surprising that the diastolic murmur persists; but we had expected that the uroporphyrin together were related in these three patients to the severity of clinical manifestations Under optimal conditions in vitro the yields of uroporphyrin from highly purified porphobilinogen have not exceeded 40% (Westall 1952), hence the sum of porphobilinogen and uroporphyrin may be a more reliable index of the biochemical disturbance which obtains

---

* A second death (case 57), unrelated to the valvulotomy ten months previously, has recently occurred.

It will be of interest to observe if and when clinical manifestations appear in case 3, and whether these will be associated with measurable quantities of urinary uroporphyrin

PERIPHERAL NEUROPATHY DUE TO ISONIAZID

REPORT OF TWO CASES

W Arthur Jones
L M S S A
SENIOR HOUSE OFFICER

G Penrhyn Jones
M D Lpool, M R C P, D C H
SENIOR MEDICAL REGISTRAR

AINTREE HOSPITAL, LIVERPOOL

One of the advantages of isoniazid in comparison with *p* aminosalicylic acid (P A S) in the chemotherapy of tuberculosis is the diminished incidence of toxicity No significant intolerance of isoniazid has been observed so far in the present M R C chemotherapy trial, although some cases have shown toxic responses to P A S (Medical Research Council 1952, 1953)

The preliminary reports on isoniazid mentioned hyper-reflexia, transient extensor plantar responses, hesitancy of micturition, vertigo, evanescent proteinuria, and occasional severe eosinophilia as manifestations of toxicity In the past year further toxic reactions have been reported, blood dyscrasias and nervous complications being the most important

Agranulocytosis has been described by Ferguson (1952) and by Varadi and Kelleher (1953) Various nervous complications include acute pellagra (McConnell and Cheetham 1952), confusional psychosis (Hunter 1952, Leitner 1952, Zabad 1953), hyperæsthesia (Pegum 1952), polyneuritis, motor weakness, and schizophrenia (Heilmeyer et al 1952), and peripheral neuropathy (Selikoff et al 1953, Counihan et al 1953)

CASE-RECORDS

Case 1 —A man, aged 23, had periodic bronchitis and asthma since the age of 12 Valvular heart disease, presumably rheumatic, had been diagnosed at 14 Two siblings died of tuberculosis

After the diagnosis of pulmonary tuberculosis in November, 1951, he spent six months in a sanatorium, and was under chest clinic supervision in October, 1952, when further extension of his disease was detected Daily domiciliary treatment was instituted with P A S 18 g and isoniazid 300 mg (5 mg per kg of body weight) After six weeks' chemotherapy he complained of hypersensitivity of hands and feet, with considerable sweating of palms and soles Muscle power gradually weakened in wrists and fingers, and dyspnœa became troublesome P A S therapy was discontinued, but, the symptoms persisting, the isoniazid therapy was also discontinued, and he was given thiamine tablets (vitamin B_1) 18 mg daily During the period of chemotherapy the patient's domestic conditions were extremely unsatisfactory, and his diet was probably deficient in first-class protein, and he received no vitamin supplements Four weeks after cessation of chemotherapy he was admitted to hospital

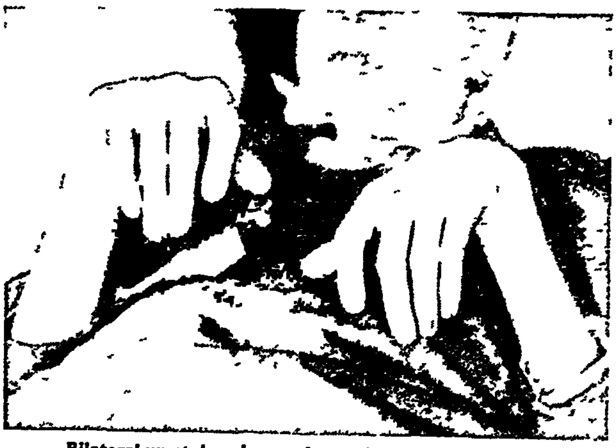
On admission his general condition was very poor, and he had persistent moderate pyrexia, pulse rate 124, and blood pressure 105/75 mm Hg A harsh systolic murmur was audible over the whole of the precordium, with apical triple rhythm Signs of congestive failure were present, with jugular engorgement and sacral œdema The liver was moderately enlarged, and ascites was detected Electrocardiography showed right ventricular preponderance and sinus tachycardia Moist sounds were audible over the whole of the chest, and radiography of the chest revealed chronic bilateral tuberculosis with considerable cavitation The heart was also shown to be enlarged Wasting of the forearms and of the small muscles of the hands was pronounced, with bilateral wrist drop Ankle dorsiflexion was also weak, and the peripheral tendon reflexes could not be elicited Passive joint movement and muscle pressure were unduly painful There was no significant loss of joint sense, but patchy cutaneous hypæsthesia was present on the front of the shins and dorsum of the feet The soles of the feet looked rather red and raw Although the patient's manner was petulant, his responses were rational and he showed no cerebral impairment

A blood count and examination of the urine were normal Sputum was smear positive for acid fast bacilli

Treatment was started with intramuscular thiamine 200 mg, which on two occasions failed to evoke a diuresis Mersalyl (2 ml) also failed to have a significant effect The patient's general condition deteriorated somewhat, the œdema increasing, with little improvement in the peripheral limb changes Mental confusion was noticed once or twice, and thickening and exfoliation of the skin on the back of the hands were thought by the staff to be due to excoriation produced by bandages holding the wrist splints These features of classical pellagra became obvious, and therapy with intramuscular nicotinamide 100 mg and mersalyl was followed by rapid clinical improvement Chemotherapy was restarted with streptomycin and P A S, the vitamin B complex being continued orally

Progress —A month after admission the signs of congestive failure had improved, the blood pressure was 120/90 mm Hg, and the pulse rate was 80 Triple rhythm, with a generalised systolic murmur, persisted There was no impairment of cutaneous sensibility, and the motor weakness had improved considerably, apart from a persisting weakness of the left wrist extensors There was some residual wasting of the peripheral muscles, and both knee and ankle reflexes were absent The chest film showed a decrease in the heart size, and the hyperkeratosis on the dorsum of the hands gradually improved

Case 2 —A girl, aged 18, had had bilateral extensive tuberculosis for three years Streptomycin and P A S were given in 1949 for six weeks with little improvement In 1952 isoniazid alone was administered for three months at home in a daily dosage of 450 mg (12 mg per kg of body weight) Again there was no significant change in either the chest film or her general condition, and a further three month course of isoniazid alone was given four months later



Bilateral wrist-drop in case 1, on admission to hospital first heart sound and the opening snap would be modified. Presumably vibration of the leaflets rather than the *actual closure or opening of the valve* is responsible for these signs. We have not noted the disappearance of a systolic murmur after valvulotomy, but in some cases a systolic murmur has been produced although unaccompanied by dynamic evidence of mitral incompetence.

Dangers in Delay

A correct decision on whether to perform valvulotomy requires a more precise assessment of mitral disease than was customary, or helpful, before surgery became possible. Without such an assessment patients may be kept under observation until the best time for operation has passed; and occasionally deterioration is rapid. At the present time, too, when many patients with mitral disease await admission to hospital for investigation or operation, there are unavoidable delays, during which lives are lost. The principal dangers are from acute pulmonary œdema, congestive cardiac failure precipitated by acute respiratory infection, pulmonary embolism or infarction, and systemic embolism. It might be thought that to patients subject to these dangers the risk from operation would be great, but in our experience this is not evident and the results of operation are often gratifying.

Since valvulotomy has only recently been established most patients in this series were operated on too late—not too late for considerable or material benefit to *accrue but too late for them to gain the fullest advantage.*

In each case, granted the opportunity, there must have been an optimal time, and the responsibility of physicians in the future is to select it. This will not always be easy; but in our view the error is likely to be on the side of operating too late rather than too soon. Once any considerable stenosis has developed, the passage of time will usually lead to progressive damage to the heart in the form of muscular dilatation and hypertrophy; damage to the pulmonary vessels in the form of arteriolosclerosis and atheroma; and damage to the lungs and liver in the form of chronic passive congestion. It bears repetition that progression of symptoms, at any stage, means that operation should be considered.

Summary

Of 200 patients with mitral valvular disease subjected to operation, 130 came from one *medical unit, and of* these the first 100 with predominant stenosis are reviewed.

Cases of all grades of severity, except those without symptoms and those with very large hearts and uncontrollable cardiac failure, were included. In the absence of contra-indications operation should be considered for every patient with mitral stenosis in whom symptoms are progressive.

The ages of the patients ranged from sixteen to fifty-nine, 14 being over fifty. 83 were female.

The more important symptoms and signs of predominant mitral stenosis are described and compared with those in 17 cases of predominant mitral incompetence. The value of the various signs in judging the advisability of surgical treatment is discussed.

In distinguishing predominant stenosis from predominant incompetence emphasis is laid on the qualities of the first heart sound and opening snap. The qualities of an apical systolic murmur and systolic expansion of the atrium are of relatively little value. Mistakes can usually be avoided by paying attention to all the relevant factors.

Radiography is indispensable. Electrocardiography sometimes gives useful confirmatory evidence. Cardiac catheterisation may be valuable in *difficult cases.*

The patients with the highest pulmonary arterial pressures tend to have a high pulmonary arteriolar resistance, tight mitral stenosis, normal rhythm, right ventricular hypertrophy, recurrent hæmoptysis, and breathless attacks but not pulmonary œdema; they seldom have auricular fibrillation. A *relatively* low pulmonary arterial pressure may be due to severe myocardial damage.

40% of the patients had established or paroxysmal auricular fibrillation. Auricular fibrillation is a disadvantage but not a contra-indication to operation. 19% who had sinus rhythm before operation developed auricular fibrillation in the immediate postoperative period. The restoration of sinus rhythm with quinidine is discussed.

Pregnancy often aggravates the symptoms and signs of mitral stenosis. Valvulotomy is sometimes an alternative to the *termination of pregnancy. The results in* 3 such cases are reported.

The outstanding unpredictable risk of the operation is embolism; but cardiotomy may be an effective method of evacuating clot from the left auricle and atrium without the production of systemic embolism.

In the present series 7 patients died as a result of the operation. The causes of death were embolism (2 cases), ventricular fibrillation, transfusion reaction, cardiac arrest, probable hepatic failure, and probable intracardiac thrombosis. 5 of these patients were severely ill before operation. 1 patient died later.

Of 74 *patients followed up for* more than three months the results are good in 66, fair in 6, and poor in 2. In 1 of the patients with a poor result a second operation has achieved better division of the commissures.

In patients with intractable œdema ligation of the inferior vena cava may prove to be a useful prevalvulotomy procedure.

It is emphasised that valvulotomy is not curative, and changes in cusps, chordæ, and cardiac muscle persist.

Team-work is necessary in the investigation and treatment of these patients and the recording of their cases. We acknowledge with gratitude the help of the staff of the cardiac unit in the Western General Hospital, the staff of the thoracic unit in the Eastern General Hospital, and the radiological staffs of both hospitals.

DIABETES AND PERIPHERAL ARTERIAL DISEASE

A CLINICAL STUDY

Robert Semple
M.D. Aberd., M.R.C.P.
FIRST ASSISTANT, PROFESSORIAL MEDICAL UNIT, MIDDLESEX HOSPITAL, LONDON

As it has long been known that arterial disease is a common complication of diabetes mellitus, I was surprised to find only 6 cases of diabetes in 100 cases of intermittent claudication due to obliterative arterial di

The object of the present study wa whether there was any difference betwe occurring in diabetics and in no investigate the prevalence and type disease in a group of diabetics.

METHO

100 unselected diabetics, a the diabetic clinic of the ined. A short clinical points noted included claudication or of rest was also made conc and angina pect recorded and the absence of the

Towards the end of the second course the patient began to complain of paræsthesiæ, "hot feelings," in the hands and feet Stiffness and numbness of the legs, with occasional shooting pains, became more pronounced Her appetite had been poor during this course of chemotherapy, improving when the isoniazid was stopped Two weeks after the cessation of isoniazid therapy there were signs of peripheral neuropathy Neither ankle reflex could be elicited, patchy areas of anæsthesia were present over the front of the legs and the dorsum of the feet, and muscle pressure was very painful Appreciation of movement and position was absent in the toes, but no significant objective change, motor or sensory, was detected in the arms

Her symptoms improved gradually, and three weeks later the signs of neuropathy were noticeably less In view of her poor general condition, gross disease, and emaciation no further chemotherapy was proposed, no vitamin supplements were given, and treatment was symptomatic

DISCUSSION

Pegum (1952), drawing attention to "burning feet" in a patient receiving 150 mg daily of isoniazid for one week only, suggested that this condition was caused by competitive inhibition of nicotinic acid by the isoniazid McConnell and Cheetham (1952) emphasised this possibility when they described a case of acute pellagra following two weeks' chemotherapy in a patient who received isoniazid 8 mg per kg body-weight Zabad's (1953) case of confusional psychosis following isoniazid therapy responded dramatically to nicotinamide administration, and probably Hunter's (1952) case was also due to conditioned nicotinamide deficiency

Dementia, dermatitis, and diarrhœa are characteristic of complete pellagra, but milder degrees of pellagra may be recognised, with pigmentation, neuritis, and ataxia (Morris 1949) Appreciation of passive movements of the toes may be lost, and muscle tenderness and superficial anæsthesia may appear (Brain 1947) Napier (1952), however, believes that probably an associated deficiency of vitamin B_1 is the cause of the neuritic signs of pellagra

The association of peripheral neuropathy with congestive cardiac failure in case 1 suggested thiamine deficiency The absence of response to vitamin B_1 and the evidence later obtained that the patient had received thiamine 18 mg daily for three weeks before admission ruled out this possibility Further, his disease progressed for a few days in hospital until overt signs of pellagra appeared The subsequent dramatic response to nicotinamide suggests that the neuropathy was directly due to a deficiency of this vitamin and possibly of other members of the vitamin-B_2 complex We also feel justified in assuming that the onset of cardiac failure at the same time as the neuropathy was related to such a deficiency, and that this was precipitated in a previously damaged heart Mersalyl alone had little influence on the œdema until nicotinamide was concurrently administered Electrocardiographic changes, such as alteration of the ST segment, occur in pellagra, and Rachmilewitz and Braun (1945) report that these disappear when nicotinic acid alone is given Weiss and Wilkins (1937) have described a case similar to ours, with dermatitis of pellagra, peripheral neuropathy, and œdema

Peripheral neuropathy alone, however, may not explain the disproportionate motor weakness in case 1 compared with the relative paucity of objective sensory changes Other members of the vitamin-B_2 complex may be involved in producing pellagra Pyridoxine (vitamin B_6) is a pyridine derivative similar to nicotinamide and isoniazid, the latter may block its action by competitive inhibition It has been shown by Hammouda and Nagi (1948) that pyridoxine deficiency may produce muscular weakness

SUMMARY

Two cases of peripheral neuropathy following isoniazid therapy are described

It is suggested that this recognised complication of isoniazid therapy is due to a deficiency of nicotinamide and possibly of other members of the vitamin-B_2 complex

We wish to thank Dr O F Thomas and Dr W D Gray for their encouragement, Dr W J Chisnall and Dr W G Merrick, who as general practitioners first saw the patients, for their help, and Mr J Wall for the photograph

DURING a clinical trial of 'Milontin' (N-methyl a phenyl-succinimide) evidence of renal damage, consisting of microscopic hæmaturia and granular casts, was discovered in half the children treated (Millichap 1952) In seven patients this side effect was slight and transient, but in three, receiving large doses of milontin, it was more severe The dose was reduced in one case, and in two the drug was withdrawn Sequelæ developed in none, and subsequent specimens of urine, examined a week or two later, were normal These findings, since confirmed by Dr G A Thompson and others (personal communications), were associated in three patients with increased frequency of micturition

Hitherto, with troxidone ('Tridione') and aloxidone ('Malidone') these microscopic urinary abnormalities have not been reported Their potential sequelæ, however, have been published as five cases of the nephrotic

nutritional state of the skin and toe-nails noted. Finally an exercise test was made, the pulsations being recorded from each foot before and after ninety seconds' vigorous dorsiplantar flexion of the foot at the rate of one per second. This is sufficient exercise to test the patency of the arteries of the thigh and leg (McDonald and Semple 1952).

Criteria for diagnosis of arterial disease of legs.—Patients with unequivocal symptoms and signs presented no difficulty. A history of typical intermittent claudication or of gangrene was regarded as evidence of arterial disease. Where these manifestations were absent the decision was more difficult. Disappearance or gross diminution of the pulsations from the foot after exercise (inverse reaction) was accepted as indicating the presence of arterial obstruction, because this response to exercise has always, in our experience, been associated with arterial obstruction (McDonald and Semple 1952). Ejrup (1948), in his extensive studies, considered that an inverse reaction was invariably associated with arterial obstruction except in cases of coarctation of the aorta or of gross anæmia. Patients in whom one or more of the peripheral pulses were absent and who also showed an inverse reaction after exercise were therefore accepted as having obliterative arterial disease, as were those in whom all pulses were present but who showed an unequivocal inverse reaction. Patients with a normal response to exercise but with absent pedal pulses presented more difficulty. Absent pulses were noted in 13% of normal young men by Silverman (1946); one or both dorsalis pedis pulses were most commonly missing. Similar findings have been reported by other workers (Morrison 1933), and a personal survey of 80 surgical patients, aged more than 40, in this hospital was in close agreement. In this work, therefore, those who were found to have either one absent pulse at the foot or both dorsalis pedis pulses absent were not considered to have arterial disease. Patients in whom both posterior tibial pulses were absent were accepted as having obliterative arterial disease, and in the majority there was collateral evidence of this (rest pain, absence of recordable pulsations at the feet, or angina pectoris).

TABLE I—COMPARISON OF DIABETICS WITH AND WITHOUT ARTERIAL DISEASE OF LEGS

$\chi^2 = 9{\cdot}883,\ n = 2,\ P < 0{\cdot}01.$

RESULTS OF SURVEY OF DIABETICS

Age and Sex

The mean age was 63·3 years, with a range of 50–79 years. 52 (52%) of the patients were women, and the age-distribution of the sexes was similar.

Prevalence of Arterial Disease

58 patients (58%) had no symptoms or signs of arterial disease of the legs. Details of these cases are shown in table I.

42 patients showed evidence of arterial disease of the legs. Symptoms of arterial disease were present in 10 patients, of whom 4 had intermittent claudication, 3 had past or present gangrene, and 3 had intermittent claudication and gangrene. The remaining 32 patients had no symptoms specifically attributable to arterial disease; the rest pain, numbness, and paræsthesiæ experienced by some of them could have been caused by diabetic neuropathy. Of these 32 patients 12 had absent pulses and an abnormal response to exercise, 13 showed normal pulses and an abnormal response to exercise, and in 7 both posterior tibial pulses were absent although no inverse reaction could be demonstrated. In some of the last-named no pulsations were recordable from the foot at rest, and an exercise test was therefore impossible. Details of these patients are shown in table I.

It will be seen from table I that the two groups are similar in most respects. The sex-distribution, the number taking insulin, and the proportion with hypertension (either systolic or diastolic) are the same. There are, however, significantly more patients with coronary heart-disease among those with arterial disease of the legs, and there are more with arterial disease in the eighth decade of life. The effect of age is shown clearly in table II, where it will be seen that the proportion with arterial disease increases each decade, and that there is a particularly sharp increase in the eighth decade. In table III is shown the duration of the diabetes in the different groups. It is apparent from this table that the occurrence of arterial disease is independent of the duration of clinical diabetes mellitus.

RESULTS OF SURVEY OF GANGRENE

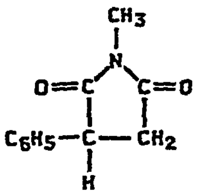
Of these 52 patients 25 were diabetic and 27 non-diabetic. Although glucose-tolerance tests were not

TABLE III—DURATION OF DIABETES IN DIFFERENT AGES, WITH AND WITHOUT ARTERIAL DISEASE

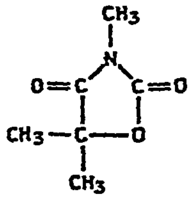
Age-group (yr.)	Total	Mean duration of diabetes (yr.)	
		With arterial disease	Without arterial disease
50–59	35	2·8 (Range $^1/_{12}$–20)	5 (Range $^1/_{12}$–24)
60–69	40	8·5 (Range $^1/_{12}$–45)	4·9 (Range $^1/_{12}$–35)
70–79	25	6·0 (Range $^1/_{12}$–19)	8·0 (Range $^6/_{12}$–20)

syndrome resulting from troxidone therapy (Barnett et al 1948, Briggs and Emery 1949, White 1949, Nabarro and Rosenheim 1952, Kelley and Panos 1952)

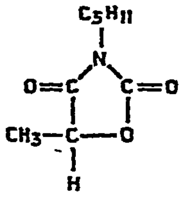
Since, as shown below, the structural formulæ of troxidone and aloxidone are closely related to milontin it seemed reasonable to postulate that their effects on the kidneys might be similar



('Milontin')
SUCCINIMIDE



TROXIDONE
('Tridione')



ALOXIDONE
('Malidone')

OXAZOLIDINEDIONES

INVESTIGATION

At the Fountain Hospital two groups of children with epilepsy were treated, one with troxidone and another with aloxidone, 0 3 g five times a day

The dose of troxidone used in this trial was the average dose used by Lennox (1945), i e, 1 5 g daily, it was smaller than the average dose of milontin producing urinary changes

Since transient albuminuria and casts are known to follow major epileptic seizures (Novick 1920), two patients in whom these occurred were excluded from the test The urine was examined microscopically on one or more occasions before treatment and weekly thereafter

The premedication specimens and those from five control children were normal.

In group 1 troxidone was given to twelve boys, aged 8–14 years Table I shows that in eight of them signs of glomerulo-tubular damage were discovered within 8 weeks of the start of treatment Red cells and granular casts were present in the urine of two patients 7 weeks after the withdrawal of troxidone In the remainder the urine had returned to normal.

TABLE II—NEPHROTOXIC EFFECTS OF ALOXIDONE IN 4 OF 8 CHILDREN TREATED

Case no	Age (yr)	Sex	Proteinuria	Microscopic hæmaturia	Granular casts	Time of onset (wk)	No of abnormal weekly specimens
1	$12^1/_2$	F	—	—	—	4	2
2	12	F	—	—	—	4	4
3	11	M	—	—	+	2	4
4	10	F	—	+	++	1	1

Group 2 consisted of eight children, aged 9–12 years, treated with aloxidone for 8 weeks In four abnormal urinary constituents were discovered Table II shows the degree of this nephrotoxic effect and the time and frequency of its occurrence in each case.

In most instances an excess of red cells or of granular casts was present while a test for protein in the urine was negative

One red cell in every high-power microscopical field was considered an abnormal number In denoting microscopic hæmaturia + was used to indicate 1–5 red cells per high-power field, and ++ 5-15 red cells The control premedication specimens of urine contained either none or very few red cells

SUMMARY AND CONCLUSION

Of twelve children treated with troxidone, eight showed microscopic urinary abnormalities Similar evidence of renal damage, hitherto unreported, was discovered in four out of eight children treated with aloxidone

To avert the more serious sequelæ of these nephrotoxic effects, regular microscopy of the urine seems desirable whenever the drug is given to children and whenever it is given in moderate or large doses

That discrimination is necessary in the use of these compounds is illustrated by two cases in which signs of renal damage persisted after withdrawal of troxidone

We wish to thank Dr Charles F Harris for his encouragement, Dr H. F B Brewer for laboratory facilities at St Bartholomew's Hospital, Dr Robert Hodgkinson for help in the preparation of this paper, Miss B Kirk for technical assistance, and the ward sisters of the Fountain Hospital for their coöperation

Preliminary Communication

THE EFFECT OF GLUTAMIC ACID ON THE COMA OF HEPATIC FAILURE

DESPITE much recent research the underlying biochemical disturbances in hepatic coma remain obscure In an earlier communication[1] the rôle of disordered amino-acid metabolism in the pathogenesis of this syndrome was emphasised, particularly with reference to glutamic-acid metabolism in the brain and the possible presence of methionine sulphoxide, a glutamic-acid antimetabolite, in the plasma and cerebrospinal fluid of certain cases of hepatic coma Glutamic acid $(COOH\ CH_2\ CH_2CH\ NH_2COOH)$ is the only amino-acid oxidised by the brain[2]; it is deaminated to α-ketoglutaric acid, which enters the Krebs cycle and therefore associates glutamic acid with carbohydrate metabolism It binds ammonia to form glutamine, which is then metabolised without liberating ammonia Waelsch[3] believed that the equilibrium between glutamic acid and glutamine in the brain might act as one of the metabolic buffers of the tricarboxylic acid cycle and also ensure an adequate supply of α-ketoglutarate However, according to Weil-Malherbe[4] the primary rôle of glutamic acid in cerebral metabolism is based on the three enzymic reactions deamination, transamination, and amidation, which are all part of an integrated system for the removal of intracellular ammonia Glutamic acid is also essential for the synthesis of acetylcholine[4] and for cation transport in the brain,[5] kidney,[6] and probably in other tissues

In view of the important rôle of glutamic acid in both cerebral and hepatic metabolism and its action in

TABLE IV—STATE OF POPLITEAL AND FEMORAL ARTERIES IN PATIENTS WITH DIABETIC AND NON-DIABETIC GANGRENE

—	Patients with femoral or popliteal arteries obstructed	Patients with femoral and popliteal arteries clear	Total
Diabetic gangrene ..	1	7	8
Non-diabetic gangrene..	16	2	18

$\chi^2 = 11{\cdot}1$, $n = 1$, $P < 0{\cdot}01$.

done in the non-diabetics to exclude diabetes, it was considered that the great majority of undiagnosed diabetics with an area of gangrene would show glycosuria on examination of the urine.

Age and Sex

Of the 25 diabetics 15 (60%) were women, whereas of the 27 non-diabetics only 3 (11%) were women. The difference between these is highly significant. The age-distribution was similar; the range in the diabetics was 54–80 years, with a mean of 67 years, and in the non-diabetics 40–85 years, with a mean of 62·7 years.

Prevalence of Intermittent Claudication

Of the 25 diabetics 6 (25%) gave a history of intermittent claudication, and 4 of these had claudication from six months to thirteen years before the onset of gangrene. Of the 27 non-diabetics 20 gave a history of intermittent claudication; 18 of these had intermittent claudication from a month to seven years before the onset of gangrene. The difference between the prevalence of intermittent claudication in the two groups is 49% ±12 (standard error) and is highly significant.

Results of Femoral Arteriography

Of the 25 diabetics 8 were investigated by this method and 10 limbs were arteriographed. The femoral and popliteal arteries were seen to be normal in 9 (90%) of these 10 limbs. In the non-diabetics arteriograms were done in 18 patients and 21 legs were so examined. The femoral and popliteal arteries were normal in only 2 (10%) of these 21 limbs, and in 2 others there was gross narrowing almost completely obstructing the femoral or popliteal arteries at some level. These details are shown in table IV. It will be seen that there is a significant difference between the two groups as regards the popliteal and femoral arteries.

The vessels obstructed in the diabetics were the anterior and posterior tibial and the peroneal arteries, although arteriographic information on these more distal vessels is less precise than in the thigh. Detailed arteriographic findings are given in tables V and VI.

In summary, arterial disease in diabetics presents first with gangrene, but in a few as intermittent claudication. The femoral and popliteal arteries are commonly not obstructed. In the great majority of non-diabetics intermittent claudication precedes gangrene, and there is usually complete obstruction of the femoral or of the popliteal arteries. In diabetics obstruction of the more distal vessels of the leg is common.

DISCUSSION

Prevalence of Arterial Disease in Diabetics

This has been the subject of many papers since Seegen (1870) first reported the common association of disease of the coronary arteries with diabetes mellitus, and since Heitz (1924) noted the association of coronary heart-disease, intermittent claudication, and diabetes.

In table VII are summarised observations made by several investigators in the past twenty-five years. From this table it will be seen that the reported prevalence of arterial disease of the legs varied widely from 50% (Pearl and Kandel 1939) to 3% (Dry and Hines 1941). Lack of standard criteria for the recognition of arterial disease explains many of these discrepancies. Rabinowitch et al. (1934), who were most insistent on the need for such criteria, accepted radiographic vascular calcification as synonymous with arterial disease, as did Jackson et al. (1949). Strictly speaking this is true, but it has been pointed out by Lansbury and Brown (1934) that such calcification does not mean arterial narrowing. Pearl and Kandel (1939), who found that more than half their diabetics had symptoms of arterial disease, accepted "mild pains" and "cramps" as indicating such a change. Naide (1945) regarded the occurrence of pain, coldness, numbness, tingling, and cramps as signifying arterial disease. These symptoms, however, result from diabetic neuropathy without arterial disease. Herzstein and Weinroth (1945) used oscillography to determine the presence of arterial disease; the absence of two pulses or the occurrence of claudication was also considered significant.

TABLE V—SITES OF ARTERIAL OBSTRUCTION SHOWN ARTERIOGRAPHICALLY IN 8 DIABETICS

Case no.	Age (yr.)	Sex	Side	Femoral arteriograms
1	54	M	Left	Left femoral and popliteal arteries normal
2	58	M	Left	Complete obstruction of whole length of left femoral artery
4	61	F	Left	Obstruction of posterior tibial and peroneal arteries; femoral and popliteal normal
			Right	Obstruction of anterior and posterior tibial arteries; femoral and popliteal normal
5	60	F	Left	Posterior tibial artery obstructed; other tibials narrowed; femoral and popliteal normal
			Right	Posterior tibial and peroneal arteries obstructed; femoral and popliteal normal
13	78	M	Right	Tibial arteries obstructed; femoral and popliteal normal
16	58	M	Right	Femoral and popliteal arteries normal
19	66	F	Right	Femoral and popliteal arteries well filled and slightly irregular; anterior and posterior tibial arteries obstructed
22	79	M	Right	Femoral and popliteal arteries clear; anterior and posterior tibial arteries obstructed above ankle

There appeared to be general agreement among these workers that the severity of the diabetes bore little relation to the occurrence of arterial disease (Rabinowitch et al. 1934, Pearl and Kandel 1939, Dry and Hines 1941, Herzstein and Weinroth 1945). The same conclusion was reached by Root and Sharkey (1936) in an analysis of the findings at 175 necropsies on diabetics and by Bell (1952) in 1559 necropsies. Mandelberg and Sheinfield (1946), investigating 128 amputated legs, reported a similar finding. The present results agree with these reports.

Opinion has been less unanimous on the relation of the duration of the diabetes to the prevalence of arterial disease. Some believe that there is a direct relation between the two (Millard and Root 1948, Herzstein and Weinroth 1945). This was denied by Pearl and Kandel (1939). The present results suggest that advancing years rather than the duration of the diabetes is the more important factor. It is worth noting in this connection Colwell's (1942) theory, from a study of insulin-requirement curves, that diabetes mellitus begins at birth and has passed through at least half its course by the time it is first observed clinically. In the present survey it was not unusual to find well-marked arterial disease of diabetic type in patients with a month's history of clinical diabetes. Dolger (1950) suggests that vascular removing excess ammonia, which may be one of the toxic factors producing hepatic coma, it was decided to try the effect of large doses of the amino acid intravenously in hepatic coma Glutamic acid was prepared for intravenous use, as the sodium salt, by the method of Mayer-Gross and Walker[7] To date it has been used in five episodes of coma in three patients with subacute or chronic liver damage It has not yet been possible to try this therapy in any patient with acute virus necrosis of the liver

CASE-RECORDS

Case 1—A man, aged 45, with long standing cirrhosis of the liver associated with ulcerative colitis, had hepatosplenomegaly, ascites, and œsophageal varices Laboratory tests showed strongly positive serum flocculation reactions, a low serum albumin level and a slightly raised serum bilirubin level He was admitted to hospital in February, 1952, after a "flare up" of his colitis There was little change in his condition until the morning of March 9, 1952, when he was found to be in deep coma There was a strong fetor hepatis and the plantar responses were doubtfully extensor Intravenous glucose therapy was started together with B vitamins Next day coma was deeper, the patient was hiccuping almost continuously, his plantar responses were definitely extensor, and he had a transient ankle clonus By that evening his condition appeared to be deteriorating, and it was decided to give intravenous glutamic acid, 23 g of the sodium salt was given at 6 P M The immediate effect was flushing, salivation, and increased depth of respiration Some four hours later the patient regained consciousness, next day he was mentally normal, and he has remained so to the time of writing fourteen months later

Case 2—A man, aged 51, was admitted to hospital after a hæmorrhage from large œsophageal varices As the laboratory tests suggested that liver damage was slight, he was considered a suitable case for surgery, and on March 25, 1952, a side to side portacaval shunt was constructed Four days after operation he became confused and was found to have increased tendon-jerks and bilateral ankle clonus, there was a strong fetor hepatis Next day, March 30, a high protein milk drip by intragastric tube was started By April 2 he was in deep coma and, besides his other abnormal reflex signs, he had developed bilateral extensor responses Fluid balance was maintained with intravenous glucose and electrolyte solutions, and on this day 23 g of sodium glutamate was added to the intravenous drip This led to a lessening in the depth of coma, and he became noisy and restless On April 4 a further 23 g of glutamate was given, and during the day he regained consciousness, although his abnormal reflex signs persisted for a further twenty four hours He progressed well until April 22, when he became mentally confused, and examination again revealed a prolonged ankle clonus Next day he was in light coma, 10 g of glutamic acid was given by gastric drip, and by the following morning his mental state was almost normal Oral glutamic acid was given until April 28, when it was discontinued On the morning of April 29 he was confused and noisy, and all the abnormal neurological signs noted earlier had returned Intravenous glucose was again started, but by evening he was in light coma, 23 g of sodium glutamate was therefore added to the drip, and next morning he was sufficiently improved to coöperate and to take food by mouth, treatment with oral glutamic acid was started again, and he was given 10 g daily for three weeks before the dose was reduced over the subsequent two weeks No further episode of coma occurred until he died at home in coma some eight months later

Case 3—A married woman, aged 61, was admitted to hospital for investigation with a history of recurrent attacks of jaundice over the previous twenty months, these had been associated with loss of weight and a gradual deterioration in her health Laboratory tests showed strongly positive serum flocculation reactions, a low serum albumin level and a high serum globulin level A firm liver was palpable just below the right costal margin, and there was a large spider nævus on the left shoulder On April 11, 1953, three weeks after admission to hospital, she became confused and did not recognise her relations She remained able to take milk and glucose by mouth, and B vitamins were given intramuscularly By April 14 there was much fluid retention and oliguria, for which she was treated with the ion exchange resin 'Katonium' (in the usual 75% ammonium form), she was also given oral glutamic acid 20 g daily Urine flow was re established by April 17, but coma was deeper, and there were extensor plantar responses and ankle clonus Treatment with intravenous glucose and electrolytes was started, and all other therapy was stopped Next day, the eighth day in coma, her condition was deteriorating, and in the evening 23 g of sodium glutamate was added to the intravenous drip During the night the coma became lighter, and by the following morning she was just able to recognise her relations and to answer simple questions That afternoon a further 23 g of glutamate was given, and by 8 P M she was fully conscious and demanding food Treatment with oral glutamic acid was started, but she became confused and aggressive about thirty six hours after emerging from coma, the dosage of the glutamic acid was therefore raised to 30 g daily, which coincided with a change to a normal mental state, and her tendon jerks and plantar responses returned to normal At the time of writing (May 19) this improvement has been maintained

DISCUSSION

The failure of oral glutamic acid to terminate the episode of coma in case 3 may well have been due to the simultaneous administration of the ion-exchange resin katonium in the 75% ammonium form Possibly this neutralised the ammonia-binding power of the glutamic acid before it could influence cerebral metabolism It has certainly been shown that ammonium ion exchange resins and ammonium chloride can produce a syndrome closely mimicking hepatic coma in patients with cirrhosis of the liver[8] Apart from this one failure glutamic acid appeared to exert a beneficial effect in five episodes of coma, on four occasions after intravenous use and once on oral administration, on one occasion also the withdrawal of glutamic-acid therapy appeared to precipitate coma This evidence strongly supports the thesis that glutamic acid influences favourably the coma that may develop in patients with subacute and chronic liver disease Whether it will have any effect on the course of acute virus necrosis of the liver remains to be seen, but in this condition it cannot act as more than a supportive therapy until such time as the virus invasion can be dealt with by the natural defence mechanisms The exact means whereby glutamic acid exerts its effect in restoring consciousness to patients in hepatic coma is not clear, it is not even certain if this action is on cerebral or hepatic metabolism, although it seems more likely that the beneficial effect is on the brain rather than the liver The most probable explanation is that glutamic acid acts by its ammonia-binding power, but its action on the Krebs cycle may also be important in view of the findings of Amatuzio and Nesbitt,[9] that the blood-pyruvate level is considerably raised in hepatic coma, and the work of Seligson et al,[10] who have found that in blood pyruvate and blood-α-ketoglutarate levels are raised in patients with liver injury Whatever the mechanism of its action, intravenous glutamic acid appears worthy of further trial in the treatment of hepatic coma In this connection the following method of administration has proved satisfactory 20 g of glutamic acid is neutralised with sodium hydroxide to give 23 g of sodium glutamate in 80 ml of water[7], this solution is added to 500 ml of 5% glucose and given intravenously over three or four hours Too rapid administration leads to salivation, flushing, and vomiting and should therefore be avoided

Not more than 23 g of sodium glutamate has been given intravenously on any one day, because this contains 130 m eq of sodium and, if used in larger doses, might lead to undesirable retention of water For oral use damage in diabetics and the insulin insufficiency stem independently from common ætiological factors.

Although the numbers in this series were small, it seems clear from the present study that increasing age is the most important factor in the development of arterial disease in diabetics, and that after the age of 70 more than two-thirds of diabetics will show arterial changes in the legs. This effect of advancing years has been noted by Pearl and Kandel (1939) and Herzstein and Weinroth (1945), but the latter also emphasise the importance of duration of the diabetes.

Prevalence of Diabetes in Peripheral Arterial Disease and its Effect on such Disease

A high prevalence of diabetes mellitus has been a prominent feature of many reports of cases of arteriosclerotic disease of the legs. In table VIII are shown figures found by different investigators.

From table VIII it will be seen that in the previously published series there was a higher prevalence of diabetes mellitus than was found by me. Lindbom (1950) recorded the lowest prevalence, and Boyd (1950), reporting more than 1000 cases of arterial disease of the legs, did not give figures for diabetes but merely referred to it as a factor to be considered in treatment. It is perhaps significant that both Lindbom and Boyd, in common with me, were reporting cases presenting with intermittent claudication, whereas this was not the case in the earlier reports, which included patients presenting with gangrene as the only manifestation of arterial disease. This is reflected in the higher prevalence of gangrene in most of these reports compared with my series, in which only 6 cases (6%) gave evidence of past or present gangrene when first seen, and 2 of these were diabetic. From a consideration of these facts it seemed possible that they were interrelated, and that the higher prevalence of gangrene recorded in other series might reflect the higher prevalence of diabetes mellitus, and that the lower prevalence of diabetes and gangrene in my series and in that of Lindbom (1950) might be explained by the selection of cases with intermittent claudication. The higher prevalence of gangrene in diabetics has been recognised (Allen et al. 1946) and was reported but not commented on by Rabinowitch et al. (1934).

The study reported here confirms this impression and suggests that arteriosclerotic disease of the legs in diabetics presents more often with gangrene, whereas in non-diabetics intermittent claudication commonly precedes such an event. Intermittent claudication affecting the calf is in most instances due to obstruction of the femoral or of the popliteal arteries; it may be deduced from this that in diabetic arteriosclerotic disease of the legs the femoral and popliteal arteries are relatively

TABLE VI—SITES OF ARTERIAL OBSTRUCTION SHOWN ARTERIOGRAPHICALLY IN 18 NON-DIABETICS

Case no.	Age (yr.)	Sex	Side	Femoral arteriogram
1	68	M	Right	Popliteal artery obstructed
			Left	Femoral artery obstructed upper third
2	48	M	Right	Femoral artery almost obstructed; tibial arteries obstructed
			Left	Femoral artery almost obstructed; tibial arteries obstructed
4	68	M	Right	Femoral artery obstructed lower third
			Left	Femoral artery obstructed upper and middle thirds
5	40	M	Left	Femoral artery obstructed
6	85	M	Left	Lower femoral and popliteal arteries obstructed
7	64	F	Left	Upper femoral artery obstructed
8	76	F	Left	Middle and lower femoral artery obstructed
9	72	M	Left	Lower femoral and popliteal arteries obstructed
10	54	M	Right	Femoral artery obstructed over entire length
14	70	M	Right	Femoral artery obstructed over entire length below profunda
15	70	M	Left	Femoral artery obstructed in lower third
16	67	M	Right	Femoral artery obstructed over entire length below profunda
17	70	M	Right	Femoral artery obstructed over entire length below profunda; anterior and posterior tibial arteries also obstructed
18	63	M	Left	Femoral artery obstructed over entire length below profunda
19	43	M	Left	Femoral and popliteal arteries normal; posterior tibial and dorsalis pedis arteries occluded
20	68	M	Right	Femoral and popliteal arteries normal; tibial arteries irregular
22	44	M	Right	Femoral artery obstructed from origin of the profunda femoris to Hunter's canal
23	66	M	Right	Femoral artery obstructed from origin of the profunda femoris to adductor opening

TABLE VII—INCIDENCE OF ARTERIAL DISEASE IN DIABETICS IN PUBLISHED REPORTS

Reference	No. of diabetics	Findings and comments
Eliason and Wright (1926)	..	20–25% of diabetics die of gangrene
Rabinowitch et al. (1934)	458 aged 50 yr. or more	44·7% showed evidence of vascular disease of legs
Rabinowitch et al. (1934)	1500 of all ages	8% with gangrene, 0·25% with intermittent claudication
Pearl and Kandel (1939)	100 (87 aged 40 yr. or more)	50% + had symptoms of vascular disease; most showed abnormalities of peripheral pulses; no relation to severity or duration of diabetes
Dry and Hines (1941)	7073	3% with symptoms and signs of arterial disease of legs; no relation to severity of diabetes
Naide (1945) ..	89 of 10-yr. standing	3% with severe symptoms of vascular disease + necrotic areas; 10% with mild (unspecified) symptoms and lesions; 23·5% with absent peripheral pulses only
Herzstein and Weinroth (1945)	249	42% with vascular disease in age-group 51–60 yr.; 63% with vascular disease in age-group 60 +; no relation to severity, but commoner in diabetics of over 5-yr. duration
Jackson et al. (1949)	75 young diabetics of 10-yr. standing	16% with vascular calcification
Reuting (1950)	50 followed since 1924	38% dead (8% of coronary disease). Of 31% alive 88% with vascular calcification in legs
Present series..	100 aged 50 yr. or more	10% with intermittent claudication or with gangrene; 32% with signs of arterial disease; 7% with clinical evidence of coronary artery disease

TABLE VIII—PREVALENCE OF DIABETES MELLITUS AND GANGRENE IN ARTERIOSCLEROTIC DISEASE OF LEGS IN PUBLISHED REPORTS

Reference	No. of cases	Prevalence of diabetes	Prevalence of gangrene
Brown (1933)	365	33%	More than 20%
Bernheim and London (1937)	99	14%	9%
Hines (1938)	280	20·3%	54%
Lindbom (1950)	74	12%	Not stated
Present series	100	6%	6%

0 5 g tablets of the free amino-acid have been used and appear to be well tolerated by these patients when given in divided doses to a total of 20 g daily

SUMMARY

The effect of glutamic acid on the coma of hepatic failure has been investigated

Five episodes of coma in three patients with subacute or chronic liver injury were treated with glutamic acid

On each occasion a return of consciousness closely followed the administration of glutamic acid, which therefore appears worthy of further trial in the treatment of hepatic coma

I wish to thank Dr J D Nabarro, Prof R S Pilcher, Prof M L Rosenheim, and Dr Cedric Shaw for permission to use glutamic acid therapy on their patients

Medical Societies

ATLANTIC CITY MEETINGS

OVER three thousand doctors met for the annual meetings of the American Federation for Clinical Research, the American Society for Clinical Investigation, and the Association of American Physicians, which were held at Atlantic City, New Jersey, from May 3 to 6 Altogether over four hundred papers were accepted for these meetings, but only eighty were read in the time available "Purely clinical" papers were in a minority, the trend being more and more towards laboratory and fundamental research In line with this, approximately 15% of all papers submitted referred to the use of radioactive-tracer techniques The tide of papers describing the pharmacology of A C T H and cortisone seems to be ebbing

Hæmatology

ABSENCE OF GAMMA GLOBULIN

C A. JANEWAY (Boston) said that in children with deficient reaction to infection, *similar to that in nephrosis, electophoresis* of the plasma had shown complete absence of the gamma globulin fraction A total of 14 such cases had been discovered, and this disorder might be more common than was initially supposed All the patients were boys with a history of multiple suppuration Arthritis and bronchiectasis were common features, and one child had had recurrent attacks of mumps In another, however, primary vaccination took normally, and revaccination showed that an immune reaction had developed The disease was probably due to a sex linked recessive gene, manifest in the male, and was apparently associated with a primary failure of gamma globulin synthesis It could be cured by weekly intramuscular injections of gamma globulin, with penicillin chemoprophylaxis, penicillin alone was ineffective

AUTO IMMUNE HÆMOLYTIC DISEASE

L E YOUNG and G MILLER (Rochester, New York) said that in auto immune hæmolytic disease the presence of sensitised red cells was apparently diagnostic, and could be detected by an anti globulin serum (the Coombs test) This, however, was not the whole story since the crises and remissions of the anæmia could vary independently of the number of sensitised red cells

L E -CELL PHENOMENON

In other papers the L E cell phenomenon came in for a good deal of attention This or very similar changes in the leucocytes could be simulated by adding a rabbit anti human granulocyte serum to a suspension of normal human leucocytes FINCH and his associates at Boston had noted clumping, vacuolisation, and rosette formation of the damaged cells, which, if they were phagocytosed by other cells, could produce a picture indistinguishable from that seen in disseminated lupus erythematosus Other reports confirmed this work

C E BUTTERWORTH (Birmingham, Alabama) had found that desoxyribonuclease, added to normal human leucocytes, might do the same thing He cautioned against the belief that the finding of L E cells was necessarily diagnostic, since he had found this change occasionally in normal leucocytes incubated without enzyme

CARRERA and associates at New Orleans had tested L E serum with leucocytes from other species, and found a wide species difference in the ability to form L E cells One particular specimen of L E serum, which gave negative results with human leucocytes, was strongly positive with those from the horse

PLATELET GROUPS

M STEFANINI and G PLITMAN (Boston) had separated 250 normal plasmas into platelet free and platelet rich fractions, and by multiple testing had found that with certain combinations platelet agglutination would occur Four platelet groups, analogous to, but distinct from, the four blood groups, were proposed, with the following distribution in the white population of North America group 1 (9%) group 2 (3%), group 3 (equals 1 + 2) (4%), and group 4 (0) (84%) Factors such as these might operate in certain cases of thrombocytopenia which exhibit progressively less response to repeated transfusions of platelets

ACTION OF THROMBIN

S SHERRY and W TROLL (Cincinnati) had confirmed that thrombin acted as a proteolytic enzyme, and had found that a synthetic substrate—tosyl arginine methyl ester (T A M E)—was split by thrombin in a characteristic fashion, and to an extent closely dependent on the amount of thrombin present Furthermore, when T A M E was added to thrombin fibrinogen systems, clotting did not proceed until all the T A M E had been split Thrombin could be accurately assayed by its T A M E splitting activity.

ANOXIC POLYCYTHÆMIA

F STOHLMAN and J C ROSE (Washington, D C) reported on a patient with cyanosis of the lower half of his body secondary to a reversal of flow in a patent ductus arteriosus The sternal marrow, which was well oxygenated, was hyperplastic, whilst the iliac marrow, which was poorly oxygenated, was hypoplastic The patient's blood showed polycythæmia This was interpreted as evidence of a humoral mechanism in anoxic polycythæmia and against the theory that direct action of anoxia on the bone marrow was the stimulus for red cell production

Immunology

GAMMA GLOBULIN IN POLIOMYELITIS

W M HAMMOND (Pittsburgh) discussed the use of purified gamma globulin in the prevention of poliomyelitis The widespread availability of this material, and the publicity that it had received, made it imperative to remember its limitations Its use against poliomyelitis was analogous to its use in the prevention of measles, with the added disadvantage that primary cases were less easy to detect, since they were commonly aparalytic Mass passive immunisation with this agent had been advocated, but he thought that this was a wasteful and useless procedure In a trial conducted under the most favourable circumstances, during the phase of rising incidence in a severe epidemic, with its use limited to the most susceptible age group, it was shown that only one in about four hundred injections actually prevented an infection He advocated reserving this material for the prophylactic immunisation of (1) contacts of paralytic cases, and (2) contacts of those who, during an epidemic, developed an undiagnosed febrile illness which might be non-paralytic poliomyelitis

RED CELLS AND INFECTION

R A NELSON (Bethesda) described an immunological phenomenon whereby normal red cells appeared to be an integral part of a reaction to invading organisms If virulent *Treponema pallidum* was added to a suspension of normal red cells in serum from a case of syphilis (antiserum) the organisms adhered to the red cells and could be centrifuged with them out of suspension If the same experiment were repeated with white cells the treponemata remained in suspension With both red and white cells, the treponemata were removed from suspension and were phagocytosed

Endocrinology

TRIIODOTHYRONINE

Several studies were reported which confirmed the work of Gross and Pitt-Rivers in England on the metabolic activity unaffected, and that the brunt of the lesion falls on the more distal vessels. This belief is strengthened by the arteriographic studies of cases of diabetic gangrene reported here. Further evidence is afforded by the finding, in 42 diabetics aged more than 50 with evidence of arterial disease of the legs, that the popliteal pulse was absent in only 6 patients, whereas 70% of 100 patients presenting with intermittent claudication had this pulse missing.

Since Buerger's (1915) dictum that gangrene in diabetics is arteriosclerotic it has been assumed by most, and stated by many, that there is no difference between arteriosclerotic disease of the legs in diabetics and in non-diabetics (Lisa et al. 1942, Wilder 1940, Samuels 1950, Pratt 1949, Allen et al. 1946). On the other hand, Warren (1938), in his extensive pathological studies of diabetes mellitus, considered that the arterial lesion in diabetic legs was distinctive, and that the vessels involved were mainly the smaller muscular arteries. This was confirmed by Bohan (1949). Lewis (1946) stated: "in diabetes, and sometimes apart from it, gangrene of a toe may result from thrombosis of the digital vessels, the pulses of the foot remaining intact"; and Learmonth (1950) referred to the digital thromboses of diabetes. Root (1952) noted that, although sclerosis of the large arteries may develop, the characteristic diabetic vascular lesion is in the smaller blood-vessels. Recognition of this may be a factor, with the antibiotics and improved surgical technique, in the increasing tendency towards the more conservative treatment of diabetic gangrene (Regan et al. 1949, McKittrick et al. 1949, Grunberg et al. 1951), compared with the high amputation recommended by earlier workers (Eliason and Wright 1926).

SUMMARY

100 diabetics, aged more than 50, were examined for the presence of obliterative arterial disease of the legs.

Signs of arterial disease were found in 42%, although only 10% had symptoms attributable solely to impaired circulation.

The occurrence of arterial disease was related to increasing age but not to the severity or to the duration of the diabetes.

A sixth of those with arterial disease of the legs had clinical coronary arterial disease.

Of 52 consecutive cases of gangrene almost half were in diabetics.

Arterial disease in diabetics presented more often with gangrene than with intermittent claudication, and the usual site of obstruction was in the more distal vessels of the leg and foot, the femoral and popliteal arteries being clear; in both these respects the reverse held true in non-diabetic arterial disease.

I wish to thank Prof. A. Kekwick for his interest and help at all times, Mr. P. B. Ascroft for giving me access to his cases of gangrene, Dr. David Sutton for the femoral arteriograms, and Dr. John Friend for his help in arranging for me to see the diabetics. Part of this work was included in a thesis accepted for the degree of M.D. of the University of Aberdeen in 1952.

BOTH urine and blood-plasma contain pepsinogen, a pro-enzyme which by acidification is converted into a proteolytic enzyme probably identical with gastric pepsin. There is evidence, reviewed by Bucher (1947), that pepsinogen reaches the urine in the following way. It is manufactured by the parietal cells of the gastric mucosa, where it can be demonstrated by Motteram's (1951) staining method. Part is secreted into the lumen of the stomach, where it is converted into pepsin by the action of hydrochloric acid, and another fraction is taken up by the blood-stream, whence it is excreted in the urine as uropepsinogen.

In the present investigation a simplified method of estimation (Fawcett 1951) based on those of Anson and Mirsky (1932), Bucher (1947), and Mirsky et al. (1948) has been used, and some factors of clinical interest have been studied. We can confirm the findings of Janowitz et al. (1950) and agree that this estimation sometimes helps in the diagnosis of duodenal ulcer from other lesions causing similar symptoms. It is also an index of adrenocortical activity, as Spiro et al. (1950) have shown.

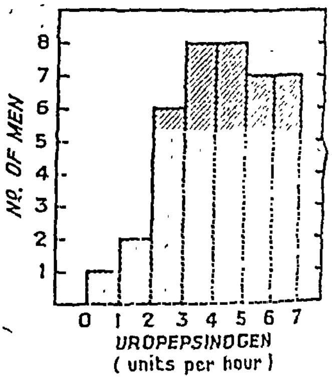

Fig. 1—Distribution of excretion of uropepsinogen (average 4·5 units per hour) in 39 normal males.

METHOD

Urine is collected for twenty-four hours or during a measured overnight period, and the volume of urine

removing excess ammonia, which may be one of the toxic factors producing hepatic coma, it was decided to try the effect of large doses of the amino-acid intravenously in hepatic coma Glutamic acid was prepared for intravenous use, as the sodium salt, by the method of Mayer-Gross and Walker [7] To date it has been used in five episodes of coma in three patients with subacute or chronic liver damage It has not yet been possible to try this therapy in any patient with acute virus necrosis of the liver

CASE-RECORDS

Case 1 —A man, aged 45, with long standing cirrhosis of the liver associated with ulcerative colitis, had hepatosplenomegaly, ascites, and œsophageal varices Laboratory tests showed strongly positive serum flocculation reactions, a low serum albumin level and a slightly raised serum bilirubin level He was admitted to hospital in February, 1952, after a "flare up" of his colitis There was little change in his condition until the morning of March 9, 1952, when he was found to be in deep coma There was a strong fetor hepatis and the plantar responses were doubtfully extensor Intravenous glucose therapy was started together with B vitamins Next day coma was deeper, the patient was hiccuping almost continuously, his plantar responses were definitely extensor, and he had a transient ankle clonus By that evening his condition appeared to be deteriorating, and it was decided to give intravenous glutamic acid, 23 g of the sodium salt was given at 6 P M. The immediate effect was flushing, salivation, and increased depth of respiration Some four hours later the patient regained consciousness, next day he was mentally normal, and he has remained so to the time of writing fourteen months later

Case 2 —A man, aged 51, was admitted to hospital after a hæmorrhage from large œsophageal varices As the laboratory tests suggested that liver damage was slight, he was considered a suitable case for surgery, and on March 25, 1952, a side to side portacaval shunt was constructed Four days after operation he became confused and was found to have increased tendon-jerks and bilateral ankle clonus, there was a strong fetor hepatis Next day, March 30, a high-protein milk drip by intragastric tube was started By April 2 he was in deep coma and, besides his other abnormal reflex signs, he had developed bilateral extensor responses Fluid balance was maintained with intravenous glucose and electrolyte solutions, and on this day 23 g of sodium glutamate was added to the intravenous drip This led to a lessening in the depth of coma, and he became noisy and restless On April 4 a further 23 g of glutamate was given, and during the day he regained consciousness, although his abnormal reflex signs persisted for a further twenty-four hours He progressed well until April 22, when he became mentally confused, and examination again revealed a prolonged ankle clonus Next day he was in light coma, 10 g of glutamic acid was given by gastric drip, and by the following morning his mental state was almost normal Oral glutamic acid was given until April 28, when it was discontinued On the morning of April 29 he was confused and noisy, and all the abnormal neurological signs noted earlier had returned Intravenous glucose was again started, but by evening he was in light coma, 23 g of sodium glutamate was therefore added to the drip, and next morning he was sufficiently improved to coöperate and to take food by mouth, treatment with oral glutamic acid was started again, and he was given 10 g daily for three weeks before the dose was reduced over the subsequent two weeks No further episode of coma occurred until he died at home in coma some eight months later

Case 3 —A married woman, aged 61, was admitted to hospital for investigation with a history of recurrent attacks of jaundice over the previous twenty months, these had been associated with loss of weight and a gradual deterioration in her health Laboratory tests showed strongly positive serum flocculation reactions, a low serum albumin level and a high serum globulin level A firm liver was palpable just below the right costal margin, and there was a large spider nævus on the left shoulder On April 11, 1953, three weeks after admission to hospital, she became confused and did not recognise her relations She remained able to take milk and glucose by mouth, and B vitamins were given intramuscularly By April 14 there was much fluid retention and oliguria, for which she was treated with the ion exchange resin '*Katonium*' (*in the usual 75% ammonium form*), she was also given oral glutamic acid 20 g daily Urine flow was re established by April 17, but coma was deeper, and there were extensor plantar responses and ankle clonus Treatment with intravenous glucose and electrolytes was started, and all other therapy was stopped Next day, the eighth day in coma, her condition was deteriorating, and in the evening 23 g of sodium glutamate was added to the intravenous drip During the night the coma became lighter, and by the following morning she was just able to recognise her relations and to answer simple questions That afternoon a further 23 g of glutamate was given, and by 8 P M she was fully conscious and demanding food Treatment with oral glutamic acid was started, but she became confused and aggressive about thirty six hours after emerging from coma, the dosage of the glutamic acid was therefore raised to 30 g daily, which coincided with a change to a normal mental state, and her tendon jerks and plantar responses returned to normal At the time of writing (May 19) this improvement has been maintained

DISCUSSION

The failure of oral glutamic acid to terminate the episode of coma in case 3 may well have been due to the simultaneous administration of the ion-exchange resin katonium in the 75% ammonium form Possibly this neutralised the ammonia-binding power of the glutamic acid before it could influence cerebral metabolism It has certainly been shown that ammonium ion-exchange resins and ammonium chloride can produce a syndrome closely mimicking hepatic coma in patients with cirrhosis of the liver [8] Apart from this one failure glutamic acid appeared to exert a beneficial effect in five episodes of coma, on four occasions after intravenous use and once on oral administration, on one occasion also the withdrawal of glutamic acid therapy appeared to precipitate coma This evidence strongly supports the thesis that glutamic acid influences favourably the coma that may develop in patients with subacute and chronic liver disease Whether it will have any effect on the course of acute virus necrosis of the liver remains to be seen, but in this condition it cannot act as more than a supportive therapy until such time as the virus invasion can be dealt with by the natural defence mechanisms The exact means whereby glutamic acid exerts its effect in restoring consciousness to patients in hepatic coma is not clear, it is not even certain if this action is on cerebral or hepatic metabolism, although it seems more likely that the beneficial effect is on the brain rather than the liver The most probable explanation is that glutamic acid acts by its ammonia-binding power, but its action on the Krebs cycle may also be important in view of the findings of Amatuzio and Nesbitt,[9] that the blood-pyruvate level is considerably raised in hepatic coma, and the work of Seligson et al,[10] who have found that in blood-pyruvate and blood α-ketoglutarate levels are raised in patients with liver injury Whatever the mechanism of its action, intravenous glutamic acid appears worthy of further trial in the treatment of hepatic coma In this connection the following method of administration has proved satisfactory 20 g of glutamic acid is neutralised with sodium hydroxide to give 23 g of sodium glutamate in 80 ml of water [7], this solution is added to 500 ml of 5% glucose and given intravenously over three or four hours Too rapid administration leads to salivation, flushing, and vomiting and should therefore be avoided

Not more than 23 g of sodium glutamate has been given intravenously on any one day, because this contains 130 m eq of sodium and, if used in larger doses, might lead to undesirable retention of water For oral use voided per hour is calculated. Results are substantially the same whichever period of collection is used. Urine uropepsinogen is stable under toluene for four days at 20°C and for fifteen days at 0°–4°C.

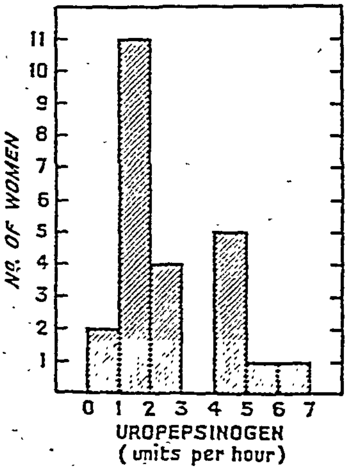

Fig. 2—Distribution of excretion of uropepsinogen (average 2·8 units per hour) in 24 normal females.

Each assay is performed in duplicate to ensure reliable results. Urine is incubated with a human hæmoglobin substrate for thirty minutes at 37°C. At pH 1·5–1·8 the possible effect of cathepsins is eliminated because the proteolytic activity of urine is stable at this pH, whereas cathepsins are not. Excess hæmoglobin is precipitated by trichloracetic acid, and the degree of proteolysis is measured by the Folin and Ciocalteau procedure. A blank determination, in which the enzyme is inactivated, accounts for chromogenic substances present in urine and substrate.

The difference between the extinction coefficients of "test" and "blank," interpreted on a calibration curve prepared from standard tyrosine solutions, is a measure of the proteolysis due to uropepsinogen activity.

Our unit of uropepsinogen is the same as that of Mirsky et al. (1948), who define it as "that quantity which, during a 10 minute incubation of the standard assay, releases 1 mg. of 'tyrosine-like' substance."

TABLE I—EXCRETION OF UROPEPSINOGEN BY PATIENTS WITH DUODENAL ULCER

Sex	No.	Mean excretion of uropepsinogen (units per hr.)
Men	62	8·7
Women	12	5·1
Total	74	8·1

Correcting for dilution and for the thirty-minute incubation period, in our assay 1 unit/100 ml. of urine ≡ 0·0015 mg. of tyrosine.

Results are expressed as the number of units excreted per hour.

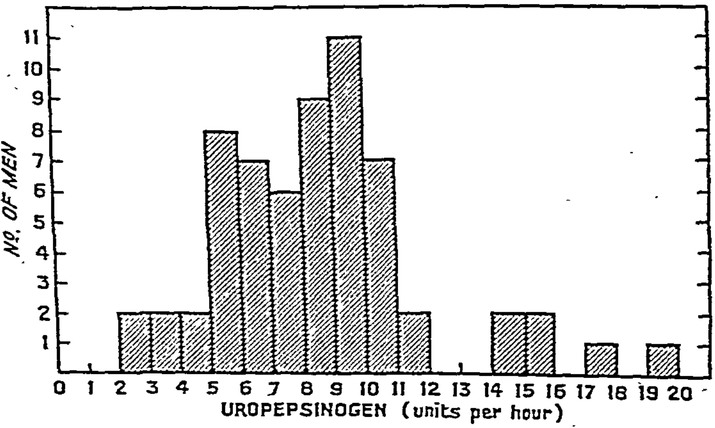

Fig. 3—Distribution of excretion of uropepsinogen (average 8·7 units per hour) in 62 males with duodenal ulcer.

RESULTS

Controls.—63 hospital patients with no clinical evidence of peptic ulcer excreted an average of 3·9 units of uropepsinogen per hour. In the 39 men the average was 4·5, and in the 24 women it was 2·8. Figs. 1 and 2 show the distribution among these patients. Comparison of 10-year age-groups showed no significant variation.

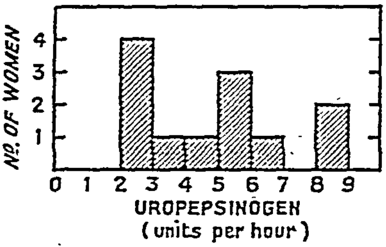

Fig. 4—Distribution of excretion of uropepsinogen (average 5·1 units per hour) in 12 females with duodenal ulcer.

Duodenal ulcer.—In 74 patients the diagnosis of duodenal ulcer was confirmed either at operation or by strong clinical and radiological evidence, and by the finding of a high gastric acidity. While the mean rate of excretion of uropepsinogen for all these patients was 8·1 units per hour, the rate for the 62 men was 8·7, and the rate for the 12 women was 5·1 (table I). The distribution of excretion-rates in men and women with duodenal ulcer is shown in figs. 3 and 4.

Gastric ulcer.—Of 21 patients with gastric ulcer, 18 excreted uropepsinogen at the normal rate. There were 11 men and 10 women in this group, but no sex distinction could be drawn within it. The other 3 of these patients excreted more than the normal amount (fig. 5).

Gastric carcinoma.—16 patients showed excretion-rates similar to the normal, though there were more low readings than in any of the other groups (fig. 6).

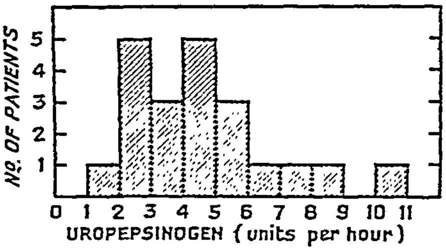

Fig. 5—Distribution of excretion of uropepsinogen (average 4·9 units per hour) in 21 patients with gastric ulcer.

Effect of operation.—The early response to a gastric operation was measured in 6 patients with duodenal ulcer and was as follows:

Mean preoperative excretion 8·0 units per hour.
Mean greatest postoperative excretion 20·0 units per hour.
Mean final excretion 5·5 units per hour.

In these patients the maximum rate of output was always reached in thirty-six to seventy-two hours. 4 cholecystectomy patients were used as controls, and the immediate effect on the mean excretion-rate was a rise of uropepsinogen from 2 units per hour to 4.

The end-effect of various gastric operations on uropepsinogen excretion is set out in table II. Gastric resection reduces the excretion-rate, but even after total gastrectomy 6 patients still produced moderate amounts of uropepsinogen. In none did it disappear from the urine, even several months after operation. Vagotomy produced no significant alteration in peptic activity shown by uropepsinogen estimation.

Effects of either cortisone or adrenocorticotropic hormone.—5 patients without clinical evidence of peptic ulcer, to whom this treatment was being given for reasons other than this study, responded with a twofold to threefold increase in uropepsinogen excretion (table III).

0 5 g tablets of the free amino-acid have been used and appear to be well tolerated by these patients when given in divided doses to a total of 20 g daily

SUMMARY

The effect of glutamic acid on the coma of hepatic failure has been investigated

Five episodes of coma in three patients with subacute or chronic liver injury were treated with glutamic acid

On each occasion a return of consciousness closely followed the administration of glutamic acid, which therefore appears worthy of further trial in the treatment of hepatic coma

I wish to thank Dr J D Nabarro, Prof R S Pilcher, Prof M L Rosenheim, and Dr Cedric Shaw for permission to use glutamic acid therapy on their patients

Medical Societies

ATLANTIC CITY MEETINGS

OVER three thousand doctors met for the annual meetings of the American Federation for Clinical Research, the American Society for Clinical Investigation, and the Association of American Physicians, which were held at Atlantic City, New Jersey, from May 3 to 6 Altogether over four hundred papers were accepted for these meetings, but only eighty were read in the time available "Purely clinical" papers were in a minority, the trend being more and more towards laboratory and fundamental research In line with this, approximately 15% of all papers submitted referred to the use of radioactive-tracer techniques The tide of papers describing the pharmacology of A C T H and cortisone seems to be ebbing

Hæmatology

ABSENCE OF GAMMA GLOBULIN

C A. JANEWAY (Boston) said that in children with deficient reaction to infection, similar to that in nephrosis, electophoresis of the plasma had shown complete absence of the gamma globulin fraction A total of 14 such cases had been discovered, and this disorder might be more common than was initially supposed All the patients were boys with a history of multiple suppuration Arthritis and bronchiectasis were common features, and one child had had recurrent attacks of mumps In another, however, primary vaccination took normally, and revaccination showed that an immune reaction had developed The disease was probably due to a sex-linked recessive gene, manifest in the male, and was apparently associated with a primary failure of gamma globulin synthesis It could be cured by weekly intramuscular injections of gamma globulin, with penicillin chemoprophylaxis, penicillin alone was ineffective

AUTO IMMUNE HÆMOLYTIC DISEASE

L E YOUNG and **G MILLER** (Rochester, New York) said that in auto-immune hæmolytic disease the presence of sensitised red cells was apparently diagnostic, and could be detected by an anti globulin serum (the Coombs test) This, however, was not the whole story since the crises and remissions of the anæmia could vary independently of the number of sensitised red cells

L E -CELL PHENOMENON

In other papers the L E -cell phenomenon came in for a good deal of attention. This or very similar changes in the leucocytes could be simulated by adding a rabbit anti human granulocyte serum to a suspension of normal human leucocytes **FINCH** and his associates at Boston had noted clumping vacuolisation, and rosette formation of the damaged cells, which, if they were phagocytosed by other cells could produce a picture indistinguishable from that seen in disseminated lupus erythematosus Other reports confirmed this work

C E BUTTERWORTH (Birmingham, Alabama) had found that desoxyribonuclease, added to normal human leucocytes, might do the same thing He cautioned against the belief that the finding of L E cells was necessarily diagnostic, since he had found this change occasionally in normal leucocytes incubated without enzyme

CARRERA and associates at New Orleans had tested L E serum with leucocytes from other species, and found a wide species difference in the ability to form L E cells One particular specimen of L E serum, which gave negative results with human leucocytes was strongly positive with those from the horse

PLATELET-GROUPS

M STEFANINI and **G PLITMAN** (Boston) had separated 250 normal plasmas into platelet free and platelet-rich fractions, and by multiple testing had found that with certain combinations platelet agglutination would occur Four platelet groups, analogous to, but distinct from, the four blood groups, were proposed, with the following distribution in the white population of North America group 1 (9%), group 2 (3%), group 3 (equals 1 + 2) (4%), and group 4 (0) (84%) Factors such as these might operate in certain cases of thrombocytopenia which exhibit progressively less response to repeated transfusions of platelets

ACTION OF THROMBIN

S SHERRY and **W TROLL** (Cincinnati) had confirmed that thrombin acted as a proteolytic enzyme, and had found that a synthetic substrate—tosyl arginine methyl ester (T A M E)—was split by thrombin in a characteristic fashion, and to an extent closely dependent on the amount of thrombin present Furthermore, when T A M E was added to thrombin fibrinogen systems, clotting did not proceed until all the T A M E had been split Thrombin could be accurately assayed by its T A M E splitting activity.

ANOXIC POLYCYTHÆMIA

F STOHLMAN and **J C ROSE** (Washington, D C) reported on a patient with cyanosis of the lower half of his body secondary to a reversal of flow in a patent ductus arteriosus The sternal marrow, which was well oxygenated, was hyperplastic, whilst the iliac marrow, which was poorly oxygenated, was hypoplastic The patient's blood showed polycythæmia This was interpreted as evidence of a humoral mechanism in anoxic polycythæmia and against the theory that direct action of anoxia on the bone marrow was the stimulus for red cell production

Immunology

GAMMA GLOBULIN IN POLIOMYELITIS

W M HAMMOND (Pittsburgh) discussed the use of purified gamma globulin in the prevention of poliomyelitis The widespread availability of this material, and the publicity that it had received, made it imperative to remember its limitations Its use against poliomyelitis was analogous to its use in the prevention of measles, with the added disadvantage that primary cases were less easy to detect, since they were commonly aparalytic Mass passive immunisation with this agent had been advocated, but he thought that this was a wasteful and useless procedure In a trial conducted under the most favourable circumstances, during the phase of rising incidence in a severe epidemic, with its use limited to the most susceptible age group, it was shown that only one in about four hundred injections actually prevented an infection He advocated reserving this material for the prophylactic immunisation of (1) contacts of paralytic cases, and (2) contacts of those who, during an epidemic, developed an undiagnosed febrile illness which might be non paralytic poliomyelitis

RED CELLS AND INFECTION

R A NELSON (Bethesda) described an immunological phenomenon whereby normal red cells appeared to be an integral part of a reaction to invading organisms If virulent *Treponema pallidum* was added to a suspension of normal red cells in serum from a case of syphilis (antiserum) the organisms adhered to the red cells and could be centrifuged with them out of suspension If the same experiment were repeated with white cells the treponemata remained in suspension With both red and white cells, the treponemata were removed from suspension and were phagocytosed

Endocrinology

TRIIODOTHYRONINE

Several studies were reported which confirmed the work of Gross and Pitt-Rivers in England on the metabolic activity

TABLE II—EFFECT OF GASTRIC OPERATION ON EXCRETION OF UROPEPSINOGEN

Operation	No. of cases	Mean excretion of uropepsinogen (units per hr.)	
		Before operation	After operation
Partial gastrectomy ..	16	6·0	4·0
Vagotomy	8	9·0	10·0
Total gastrectomy	6	4·5	2·0

Pernicious anæmia.—In the only available inpatient with this disease the urine showed no peptic activity.

DISCUSSION

Diagnostic Value

Most methods used in the diagnosis of gastroduodenal disease are subject to limitation in accuracy or cannot be used in seriously ill patients. We have found this test useful when the usual investigations could not be done or had failed to help. For example, the problem of a patient with gastro-intestinal hæmorrhage of unknown origin may be solved by finding increased excretion of uropepsinogen. Duodenal ulcer, rather than œsophageal varices, is likely to be responsible. In pyloric stenosis of possibly malignant origin a duodenal ulcer may likewise be detected as the cause. Only 1 of 16 patients with gastric carcinoma had an increased excretion of uropepsinogen (fig. 6). On the contrary, there is a tendency towards a low excretion-rate in these patients which, though it is hardly of diagnostic value, may be of interest as a possible effect of the low-protein diet commonly taken by them. Bucher (1947) found that this effect is produced by such a diet in women.

TABLE III—EFFECTS OF GIVING EITHER A.C.T.H. OR CORTISONE TO FIVE PATIENTS WITHOUT CLINICAL EVIDENCE OF PEPTIC ULCER

Drug	Mean excretion of uropepsinogen (units per hr.)	
	Resting level	Acting level
A.C.T.H.	3·0	8·5
Cortisone	1·0	3·0
,, ...	3·0	9·0
,, ...	4·0	10·0
,, ...	9·5	14·0

Effect of Surgery

Since pepsin is a sine qua non in the causation of gastroduodenal ulcer, it is useful to inquire what factors affect its production. Factors which reduce the amount of pepsin may well be favourable to the healing of ulcers. We find that such a reduction follows gastric resection but not vagotomy and gastro-enterostomy. The level which remains after total gastric resection suggests that some of the uropepsinogen may be related to extragastric sources. It is noteworthy that the gastro-intestinal defect of pernicious anæmia is associated with a total disappearance of uropepsinogen (Farnsworth et al. 1946).

We believe that the immediate postoperative response may be due to handling of the stomach at operation, and a similar view has been taken by Hirschowitz (1950). A further factor may be the stimulus provided by adrenocortical activity which follows surgical operations. Our findings, like those of Spiro et al. (1950), are that there is increased uropepsinogen elimination in patients given adrenocorticotropic hormone (A.C.T.H.). They observed this effect within twenty-four hours of giving A.C.T.H. to normal patients, but in those with an already increased rate of excretion the rise was delayed. If A.C.T.H. alone was responsible, the change might not be expected in the early urine collections after operations for duodenal ulcer. In fact, the highest readings we have obtained were those from urine excreted on the second postoperative night in patients with duodenal ulcer. Since nothing comparable was seen in similar studies on the 4 cholecystectomy patients, the early uropepsinogen flux may be due to a direct gastric mechanism. The manipulation which usually accompanies operations on the stomach may be responsible, for in patients with duodenal ulcer the stomach is already manufacturing more than the normal amount of uropepsinogen.

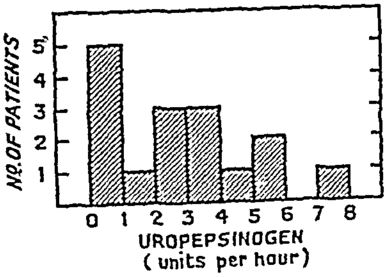

Fig. 6—Distribution of excretion of uropepsinogen (average 3·1 units per hour) in 16 patients with gastric carcinoma.

SUMMARY

A simplified method for estimating uropepsinogen is described.

The excretion of uropepsinogen has been estimated in 180 hospital patients.

Active duodenal ulcer is associated with an increased rate of excretion. This helps to distinguish (1) a duodenal ulcer from other causes of hæmatemesis, (2) a duodenal ulcer from a gastric ulcer or carcinoma, and (3) a duodenal ulcer from other sources of dyspepsia, such as the appendix.

There is a sex difference in the duodenal-ulcer patients corresponding to that seen in normal persons.

The response to various surgical operations has been studied.

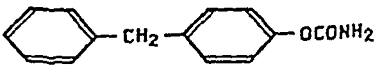
TREATMENT OF OXYURIASIS WITH DIPHENAN

LYNETTE M. DOWSETT
M.D. Lond.
OF THE PUBLIC HEALTH LABORATORY SERVICE, NORWICH

A. E. BROWN
M.D. Lond., D.P.H.
ASSISTANT COUNTY MEDICAL OFFICER, NORFOLK COUNTY COUNCIL

DURING a study of oxyuriasis in children at school A we gained the impression that diphenan was a less effective remedy than previous reports had led us to suppose. We accordingly extended our investigation to school B, and we now present our findings at these two schools.

Chemically diphenan is *p*-benzyl-phenyl-carbamate:



There are various proprietary preparations of the drug and most of the early studies were made in Germany with one of these, 'Butolan.' Diphenan is an official preparation appearing both in the *British Pharmacopœia* and the *British Pharmaceutical Codex.*

of triiodothyronine in myxœdema It now seems clear that this compound, not *l* thyroxine, is the hormone naturally active at tissue level Its effects are about five times stronger and are also more rapid in onset than those of *l* thyroxine, but they do not persist as long S P Asper and his associates at Baltimore had found that a myxœdematous patient could be cured by the new hormone with little or no increase in the titre of serum protein bound iodine R W Rawson et al (New York) confirmed this They had found that I¹³¹-labelled triiodothyronine disappeared from the circulation *much more rapidly than similarly labelled thyroxine*

FRUCTOSE FOR DIABETES

Several speakers attested to the advantages of giving fructose in the treatment of diabetic ketosis This sugar can participate in the glycolysis cycle without conversion to glucose or the participation of insulin J H Darragh et al (New Haven), for example, had noted that the intravenous fructose tolerance of patients at the height of diabetic ketosis was normal shortly after the institution of treatment with insulin and saline Glucose given under the same circumstances resulted in a prolonged rise in the serum concentration of this sugar A solution containing 2 5% fructose and 0 45% saline was given intravenously to six patients, and it seemed that there was a more rapid correction of the ketosis and of the dehydration than had previously been possible.

LOCALISATION OF INSULIN

R H Williams (Seattle) had injected insulin labelled with I¹³¹ and shown that this hormone localises particularly in the liver and the kidney Within the kidney it occurred almost entirely in the cells of the proximal convoluted tubules Such kidney localisation could be inhibited, in part, by the simultaneous administration of glucose or by growth hormone This method was a useful marker as to where the insulin appeared to be going, but must be checked by bio assay to verify that what was traced actually was insulin

ACTION OF GROWTH HORMONE

E Shorr et al (New York) reported on the metabolic effects of crystalline growth hormone given to two pituitary dwarfs Nitrogen, phosphorus, and calcium retention were produced, along with a rise in the glomerular filtration rate and a reversible insulin resistant diabetes Both patients resumed the growth rate normal for their age The effect was somewhat variable and tended to decrease the longer the hormone was given In one case there was a paradoxical resumption of its effect on withdrawal

STEROIDS

L Hellman et al (New York), by simultaneously administering differentially labelled acetate, cholesterol, and testosterone, had traced the main pathways for synthesis of the steroid compounds in a patient with a complete biliary fistula (thus obviating reabsorption from the gut) They showed that steroids of biological interest—biliary cholesterol, plasma cholesterol, cholic acid, testosterone, and other steroid hormones—could be derived both from dietary cholesterol and from acetate, and that these compounds seemed to have a common pathway for most of their synthesis Administered testosterone was converted into its urinary metabolites without the intervention of an enterohepatic recirculation The steroid nucleus, once formed, did not seem to be completely ruptured in its metabolism, since no labelled carbon dioxide could be detected in the expired air

F H Tyler et al (Salt Lake City), measuring blood levels of 17 hydroxy corticosteroids had found that certain stresses, such as the injection of adrenaline or of insulin, which produced eosinopenia *might have no effect on the amount of* the circulating adrenal corticoids However, after surgical operations, or other "life threatening" stress there might be a considerable rise in blood levels of these hormones, much in excess of what could be produced by maximal stimulation of the adrenals with intravenous A C T H

G W Thorn (Boston) had confirmed these results by assay of the urinary metabolites of compounds E and F He also noted the dissociation between the output of adrenal steroids and eosinopenia In one experiment in which the subject rebreathed into a Douglas bag with CO_2 absorber to the point of anoxia and unconsciousness, there might be a considerable increase in the output of *steroids* without significant eosinophil fall Thus it seemed that steroids other than those of *adrenal origin* contribute to the rise in the blood levels seen as a response to stress and possibly changes in the utilisation of these hormones might be a factor explaining the dissociation seen between eosinopenia and steroid output

C P Rhoads (New York), reporting the work of the late Konrad Dobriner, noted that abnormal steroid found only occasionally in patients with adrenal disease and never in normal subjects (even after A C T H stimulation) was frequently present in the urine of patients with rheumatoid arthritis and in such patients its amount could be increased by giving A C T H It was suggested that the presence of this abnormal steroid—17-hydroxy pregnenolone—was evidence for the existence of a primary adrenal defect in rheumatoid arthritis

TEST OF THYROID FUNCTION

R P Levy et al (Cleveland) described a thyroid function test involving a single-injection of thyrotropic hormone, measuring the results in terms of the serum protein bound iodine, and the I¹³¹ uptake The advantage of this test was that it measured thyroid reserve as well as current function

Cardiovascular Studies

CARDIAC OUTPUT

I Starr (Philadelphia) gave an interesting demonstration of his preparation simulating cardiac function at necropsy The cadaver heart was perfused in situ with blood from a large syringe actuated by a piston whose stroke and velocity could be accurately controlled. Simultaneous ballistocardiographic records were obtained The method was applied in many subjects and a large body of data built up, giving the cardiac output in relation to many variables such as body-build, pulse rate, and blood pressure By applying the method of multiple regression to the data, a *most interesting relationship* was established—the cardiac output in man could be calculated with excellent reproducibility from a formula derived from three simple clinical observations the diastolic blood pressure, the pulse pressure, and the body surface area The degree of accuracy probably compared quite favourably with more complicated catheter techniques

VALVULOTOMY IN PREGNANCY

C F Burwell (Boston) cautioned against the too ready use of mitral valvulotomy during pregnancy This operation was not a satisfactory alternative to termination when cardiac failure threatened to supervene during pregnancy in a patient with mitral stenosis, since benefit was not always *forthcoming and might be delayed for several weeks* Moreover the danger of congestive failure increased up to the end of the second trimester, after which time it gradually declined Mitral section should be done before pregnancy if possible, so as to improve the prognosis for pregnancy, or, if the patient was already pregnant, every effort should be made to get her through pregnancy without operation If operation had to be done *termination was the operation of choice,* and mitral section should be reserved for those bad risk cases where termination was not acceptable In any case mitral section should not be done in the last two months of pregnancy

ORTHOSTATIC PULSUS ALTERNANS

W M Daily and R F Sheffield (McKinney, Texas) described orthostatic pulsus alternans in three *patients* with organic heart disease Alternation was present only in the erect or semi erect position, and could be abolished by any measure which increased the return of blood to the heart, such as lying horizontally, immersion in water, infusions of blood or noradrenaline, or moderate exercise It could be provoked by measures which reduced the return of blood to *the heart, such as standing up, venesection, or the application* of venous occlusive tourniquets to the limbs It seemed that in this condition weakened heart muscle did not contract maximally except under conditions of increased initial stretch such as were provided by increased return of blood to the heart or the incomplete emptying of a previously weak beat

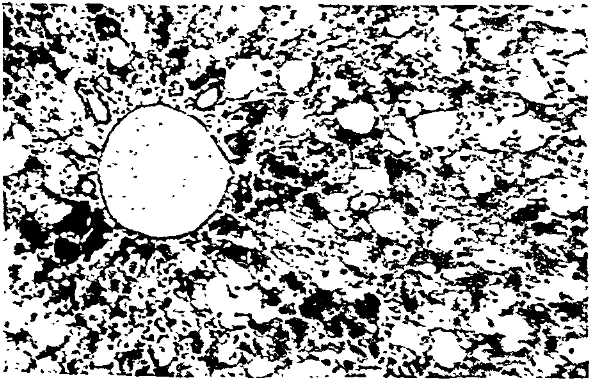
BLOOD VOLUME IN CONGESTIVE FAILURE

J F Ross et al (Boston) had measured the blood volume of dogs before and after the induction of congestive cardiac failure by operative tricuspid incompetence and pulmonary stenosis *Despite the* congestion and increased pressure in the systemic veins the blood volume, as measured by the radioactive chromium tagged red cell method, and by the Evans blue dye method, or by viviperfusion to remove all vanced fibrosis of the whole group but also presented vere cellular changes.

In contrast to the widespread cellular alterations in is group were the practically negligible changes seen the control rats receiving cortisone without carbon trachloride. Vacuolation, if present, was minimal in ctions stained with hæmatoxylin and eosin, and ballooning" was completely absent (fig. 4).

DISCUSSION

The bromsulphalein-retention test, as used here, can be pplied even to hæmolysed or turbid sera (Ahmad and razer 1952). An increase in turbidity caused by cortisone, milar to that of "fasting sera" observed in patients Adlersberg et al. 1952) or in rabbits (Rich et al. 1951) eated with cortisone or with adrenocorticotropic ormone, can therefore be discounted as an explanation f the increased retention values found in the animals eceiving cortisone and carbon tetrachloride. Antopol 1950) has described necrotic foci in the liver parenchyma f mice receiving large doses of cortisone. No such changes were observed in the cortisone-treated control rats in the present experiment; nor did cortisone have any deleterious effect on the elimination of bromsulphalein in that group of rats. This is in keeping with the experience of clinical observers that neither liver function, tested by the standard tests now in use, nor liver structure is much altered in cortisone-treated patients (Holmes et al. 1950, Goldner et al. 1950). Since, therefore, cortisone alone appears to have no obvious effect at the levels given in the present experiment, and since the impairment of liver function in rats receiving cortisone with carbon tetrachloride is considerably more severe than in those treated with carbon tetrachloride alone, the conclusion appears justified that cortisone, in the doses given here, increases the rats' susceptibility to chronic poisoning with carbon tetrachloride. This conclusion is confirmed by the histological observation that, at the cellular level, the liver lesions in both groups differ only in degree but not in kind.



ig. 3—Rat no. 6 (twenty-one injections of carbon tetrachloride; cortisone 50 mg. in ten days): extension of lesions to the cells round portal tract. (5% formol-saline solution. Hæmatoxylin and eosin. ×100.)

The characteristic zonal distribution of the lesion produced by carbon tetrachloride has been considered to be due to the vascular architecture of the liver. Increasing the dose of carbon tetrachloride only leads to an extension of the lesions (Glynn and Himsworth 1946, Himsworth 1947). The mosaic-like character of the lesion produced by carbon tetrachloride given with cortisone makes it increasingly difficult to trace this peculiar pattern, which suggests that the vascular factor may have been supplanted by some other factor. Several possible ones spring to mind in an attempted explanation of this effect of cortisone. It is well known that overdoses of this hormone in the rat lead to decreased consumption of food, rapid loss of weight, a negative nitrogen balance, an activation of fat-metabolism, and, according to Meites (1952), an increase in nutritional requirements. Sufficient experimental evidence is available to show that all these factors, either singly or combined, can increase the susceptibility of the rat towards carbon-tetrachloride poisoning (Forbes et al. 1941, Post et al. 1942, György et al. 1946, Drill 1952). Probably a better understanding of the way in which these factors act would clarify the effect of cortisone described here.

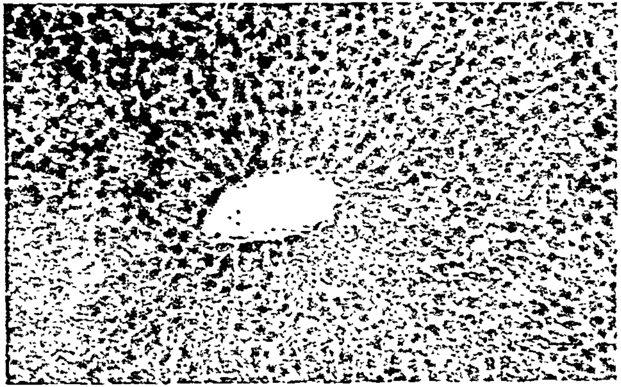


Fig. 4—Rat no. 26 (cortisone 90 mg. alone in ten days): liver cells show minimal changes. A central vein is seen in centre of section. (5% formol-saline solution. Hæmatoxylin and eosin. × 100.)

SUMMARY

Cortisone has little effect on the bromsulphalein-retention test in the normal rat, but produces considerable deterioration if given to rats treated with carbon tetrachloride for seven weeks.

The histological picture showed more widespread liver damage in these rats than in a control group treated with carbon tetrachloride only.

Cortisone increases the susceptibility of the rat's liver to chronic damage by carbon tetrachloride.

We wish to thank the Medical Research Council for the cortisone, and Mr. M. Sharradd for his technical assistance.

"... although our surgeons are as keen on early post-operative ambulation as those in the United States, this does not apply to the obstetric service. ... Strict bed rest for the parturient mother is still insisted upon. Ostensibly, this is because more importance is laid upon obtaining rapid involution of the uterus than upon the danger of venous thrombosis, but my friend suspected that there is a more subtle reason: he believes that we British doctors are more subservient to our nursing colleagues than we care to admit.—Dr. JOHN LISTER, *N. Engl. J. Med.* 1952, 247, 914.

Fitness to Drive a Vehicle

THE section of general practice met on Dec 17, under the chairmanship of Dr E P SCOTT, president of the section, to discuss Fitness to Drive a Vehicle

Dr R D SUMMERS, a divisional police surgeon in the Metropolitan area, said that in Great Britain during 1951 there had been 1309 road accidents thought to be caused by drivers who were under the influence of alcohol Many such drivers escaped conviction because the reluctance of the courts to find the accused guilty made the police unwilling to press the charge He himself did not certify some 35% of drivers referred to him as being under the influence of alcohol The charge, under section 15 of the Road Traffic Act of 1930, was concerned with being under the influence of alcohol or drugs to such an extent as to be unable to take proper charge of a motor vehicle The phrase about being in charge was sometimes rather unfairly interpreted, for a motorist who felt himself the worse for drink and who stopped his car to get into the back seat for a sleep was still technically in charge of the vehicle and could therefore be convicted of an offence The police surgeon, or the private doctor whom the accused person could call to examine him, must make a complete and thorough examination For this the consent of the accused must be obtained, and it was wise to have a witness to this consent and to the subsequent examination It was not unknown for the accused to assault the police surgeon or to attempt to escape from custody The pulse-rate should be taken at both the beginning and the end of the examination, during alcoholic intoxication the pulse was full and bounding, with a rate between 100 and 140 Full notes should be taken at the time, and every system thoroughly examined, particular attention being paid to any impairment of muscular coordination, the state of the pupils, and general behaviour It should be remembered that defending counsel could completely destroy the value of a careful clinical examination by disclosing, during cross examination, some gap in the doctor's observations For instance, the doctor might have made careful notes of the state of the pupils, but a jury would be led to think his evidence worthless if he had to admit in court that he did not know the colour of the eyes The history of any previous illnesses should be noted, and the events leading up to the accident, especially the taking of food and drink, should be investigated Evidence of the present mental state, speech, gait, and writing should be recorded Dr Summers usually asked the accused to copy a section of the Highway Code relevant to his charge, it was important to produce any specimen of handwriting in court The doctor must confine himself to the condition of the accused at the time when he examined him, and refuse to be drawn into speculations about his state at the time of arrest, which might be an hour or more previously The accused might ask for his own doctor or any other doctor to be called to examine him, as a defence against the findings of the police surgeon Such additional examinations did not come under the provisions of the National Health Service, and any doctor was entitled to refuse, or to charge a fee for his attendance If the police surgeon, having examined the accused, did not consider him to be under the influence of drink, the police very seldom prosecuted When the driver was found to be under the influence, the charge was heard next day in a magistrate's court The accused might be granted a remand to apply for legal aid, or he might elect to go for trial by judge and jury at the County Court, or to be tried by the magistrate

Dr F E CAMPS said that he thought the main duty of the doctor was to exclude the presence of organic disease, for if no disease was found to account for abnormal behaviour, and it could be proved that the person had taken alcohol, then it was a reasonable inference that his inability to control a vehicle was due to the alcohol Several drugs simulated the effect of alcohol on judgment and coordination, but it was equally an offence to be under the influence of drugs unless it could be shown that they had been taken in normal dosage in the ordinary course of medical treatment The barbiturates, nowadays widely prescribed, were commonly blamed for inability to control a vehicle, and lately the anti histamines had joined them, whilst diabetics taking insulin often pleaded hypoglycæmia in defence In one case alkalosis had been brought forward as defence by a man suffering from a gastric ulcer who had taken several spoonfuls of sodium bicarbonate—and also a large quantity of whisky

Any organic nervous disease causing incoordination, such as states of chronic cerebral contusion ("punch drunk"), acute concussion, epilepsy, vertigo from any cause, and Ménière's disease, might be the basis of a defence

Dr Camps thought that the behaviour of the accused at the time of examination was the most important point for the police surgeon to note Most private doctors were for obvious reasons, loth to attend even when they were asked to see their own patients They also were afraid of being involved in a legal case, mainly because of having to face cross examination by counsel—which should be no cause for worry Others, however, disliked hanging around courts waiting for the case to be heard, this could be avoided by approaching the clerk if necessary

Mr L C NICKOLLS, director of the New Scotland Yard laboratory, spoke of the value of the tests for estimating alcohol in blood and urine, which were chiefly corroborative of common-sense observation If a graph were drawn of the percentage of alcohol in the blood of drivers charged with being "drunk in charge," the peak of the curve would be at about 0 3%, for at this stage of intoxication a driver would draw attention to himself by swerving about the road or hitting something, for higher concentrations the curve declined, because at this stage the driver would be in the ditch or in coma Mr Frederick Mead, a Metropolitan magistrate, used to say that there was nobody like an experienced police sergeant for judging whether a man was drunk The doctor had to remember that he contributed only part of the procedure, it was for him to give his medical evidence, but it was the court's responsibility to decide whether the accused was under the influence of drink

Mr Nickolls agreed with Dr Camps that the occasional drinker who had a few too many was a much worse menace than the habitual toper He had known drivers who were drunk when they learnt to drive and would probably have been completely unable to drive if they had ever been sober

If blood or urine was collected for an alcohol estimation, it was essential to make sure that the receptacle had not been cleansed with spirit or 'Dettol', the same applied to hypodermic syringes and needles

There was great difficulty in obtaining convictions unless one had a cast iron case Magistrate, judge, and juryman were all reluctant to convict, for each one felt "There but for the grace of God " One had literally to shame them into giving a conviction, and the doctor should remember that he had a duty to the public

Dr R D LAWRENCE spoke of the diabetic driver In 1927 he and Dr Otto Leyton had discussed with high police officials the question of the diabetic's fitness to drive, and it had been decided that patients taking insulin were safe as drivers From time to time hypoglycæmia gave rise to a road accident, but such cases were relatively infrequent Any diabetic on insulin, especially if he was taking the long acting zinc protamine blood from the body, showed no increase. These results provoked considerable discussion, since they were contrary to clinical experience of congestive failure in man. It was pointed out, however, that this condition of pure right-sided heart-failure without pulmonary disease or anoxia did not have its counterpart in man and results in the two species were not directly comparable.

BIOCHEMICAL CHANGES IN HYPERTENSION

L. TOBIAN and J. BINION (Boston) had clinically analysed various tissues of rats in which hypertension had been induced by operative stenosis of the renal artery. Whereas brain and skeletal muscle tissues showed insignificant changes after the induction of hypertension, the media and intima of the aorta showed much increase in water, sodium, and potassium, and decrease in magnesium. There was evidence that these changes were predominantly intracellular. They could be discovered in operated animals even before hypertension was apparent, and therefore seemed to have some causal relationship to the increased vascular tone and tension in this condition. G. A. PERERA (New York) had found that potassium-deficient diets produced a small but significant amelioration of hypertension in man, and the beneficial effects of sodium restriction in this disease are well known.

PERIARTERITIS

M. A. BLANKENHORN et al. (Cincinnati) gave a classification of the forms of arteritis, and gave reasons for distinguishing classical periarteritis nodosa from hypersensitivity arteritis of the kind that could be induced experimentally in animals and occasionally followed sulphonamide ingestion in man. They believed that the difference was important prognostically, hypersensitivity having the better outlook. In this latter condition the arterial lesions were widespread, were all of the same age, and were found equally throughout the parenchymatous tissues of organs as well as in the hilar region, which was the classic site for periarteritis. In this condition eosinophilia did not occur, whereas in periarteritis nodosa it did. By these and by various other criteria the two conditions could be sharply differentiated.

HYPERTENSION DUE TO VASCULAR RENAL LESION

J. E. HOWARD et al. (Baltimore) read an interesting paper describing *four instances of malignant hypertension*, due apparently to a vascular lesion of one kidney, which cleared up completely when the kidney was removed. Ordinary tests of renal function might fail to reveal any impairment, or impairment of function in the affected kidney might be minimal. In one case the only evidence of abnormality was a constriction of the renal artery on arteriography; even microscopically the kidney that was removed showed no detectable changes. The maximum time between the apparent date of onset and cure by nephrectomy was about nine months.

Miscellaneous

OBSERVATIONS ON OSTEOPOROSIS

P. E. HENNEMAN and his associates (Boston) presented studies in which five patients with osteoporosis received 50 g. of human serum-albumin daily for from nine to thirty days. After twenty days the urinary output of calcium had fallen almost to zero, and metabolic studies suggested that all the retained calcium had been converted into bone. The mechanism of this action was not understood, but albumin might be a transport form of bone-matrix precursor. The amount of calcium retained, which varied from 41 to 199 mg. per day, compared favourably with figures for postmenopausal osteoporosis treated by œstrogen.

INFECTIOUS HEPATITIS

Two carefully controlled studies on infectious hepatitis were presented by a Harvard group working at the American Army Hepatitis Centre at Kyoto, Japan. They had tested: (1) enforced vigorous exercise early in convalescence as against exercise late in convalescence; (2) strict bed rest as against "ad-lib." bed rest; and (3) an enforced diet supplemented by extra choline, fat, protein, and vitamins as against an "ad-lib." hospital diet. Patients were assigned to the treatment groups at random and their progress was followed by carefully standardised clinical and laboratory observations. Patients on the supplemented diet convalesced seven days earlier than the others: the enforcement of exercise or of strict bed rest made no apparent difference to the outcome. In another study it was found that the improvement caused by the supplemented diet was due solely to the higher proportion of protein that it contained; and this was effective in the first week of treatment.

SYNDROME WITH ECK FISTULA

W. MCDERMOTT and R. D. ADAMS (Boston) reported a syndrome of episodic stupor and coma in a man with an *anastomosis between the portal circulation and the inferior vena cava* that had been produced at operation for carcinoma of the head of the pancreas. This appeared to be the first time that this type of anastomosis (an Eck fistula) had been produced in a patient who did not have either liver disease or an established collateral circulation. Convalescence was punctuated by a series of episodes varying from impairment of consciousness to deep coma. The onset was acute, and without obvious cause. The condition might last a few days, then clear up entirely and rapidly. Distinct electro-encephalographic changes, also reversible, occurred. The only consistent biochemical alteration was in the blood-ammonia, which rose sharply at the onset of each episode of stupor. The condition could be precipitated by giving ammonium salts, urea, or a high-protein diet, and in this respect resembled the so-called meat intoxication sometimes seen in Eck-fistula dogs. Protection against these attacks was afforded by a low-protein diet and by phthalylsulphathiazole to suppress intestinal *urea-forming organisms*. Elevation of the blood-ammonia content could not as yet be regarded as the cause of this condition, although it was a constant accompaniment of it. The condition might be allied to the so-called hepatic coma.

Reviews of Books

Proteins and Enzymes

Lane Medical Lectures. KAJ ULRIK LINDERSTROM-LANG. Stanford, Calif.: Stanford University Press. London: Oxford University Press. 1952. Pp. 116. 24s.

Dr. Linderstrom-Lang has been well known all over the world for many years for his ingenious studies of the distribution of enzymes inside single amœbæ, sea-urchin eggs, and other microscopic cells. From the *chemistry department of the Carlsberg Laboratory* in Copenhagen, which he directs, have come investigations of the enzymes present in the intestine of the clothes-moth larva, which enable it to digest hair and wool, and surveys of the distribution of pepsin and certain peptidases in different cells and layers of the gastric and duodenal mucosa. At the same time he has pursued the problem of the structure of proteins and the precise way in which such enzymes as pepsin exert their digestive action. These five lectures, given at Stanford University, California, in October, 1951, summarise the contributions of his school in these twin fields of enzyme biochemistry and relate them to the work of others. They provide a useful introduction to micro-techniques which permit the measurement of the quantities of different enzymes in as little as $^1/_{50}$ of an amœba, and which can be applied to liver biopsy specimens and other pathological material. They also contain many suggestions stimulating for the biochemical specialist, who will find the book gracefully written. But all medical research-workers, and particularly pathologists, may find something of value. As biochemical knowledge grows, and histochemistry develops in step, the post-mortem histology of the routine hospital pathologist is likely to give place to enzyme assays on cells and tissue sections which will provide a more dynamic functional picture of what has gone wrong. Dr. Linderstrom-Lang has laid much of the groundwork for this development.

Manual of Clinical Allergy

JOHN M. SHELDON, M.D., professor of internal medicine, University of Michigan; ROBERT G. LOVELL, M.D., instructor in internal medicine; KENNETH P. MATHEWS, M.D., assistant professor of internal medicine, University of Michigan Medical School. Philadelphia and London: W. B. Saunders. 1953. Pp. 413. 42s. 6d.

OWING to the close relation between experimental and clinical allergy most textbooks and reference books suitable for the allergist contain detailed discussions of both aspects. This book provides a common-sense

E II R

June 2, 1953

When all the people with one voice
Acclaim the Coronation day,
Each craft and calling fitly may
In its own way
Rejoice,
And its especial homage pay.

Our forefathers' untutored art
Sought healing in the touch of kings,
Yet truth lay at their legend's heart,
For we have felt the touch that brings
Health to the nation, we have seen
The greatness and the grace
Of Britain in her Queen

God save the Queen!
What meaning has that prayer
For us who know that monarchs wear
An unseen crown of care,
That kingship's tasks
Are lifelong, and through life is paid the price
Unceasing service asks?

How better can we pray
Than that, when she shall come
At close of day
Into the gay serenity of home,
There she may ever find
The best of medicines the spirit knows—
A quiet mind
And, at the heart of everything, repose?

W R B

practical survey of the clinical approach. The objective is somewhat blurred, however, for the useful 51-page discussion of pollen identification belongs rather to a reference work, while the scanty 4-page discussion of the basic mechanisms could have been extended to cover the basic facts essential for an adequate understanding of a growing subject. The value of the clinical material is enhanced by the omission of references to much vague and unsatisfactory clinical literature which are found in larger volumes. With allergy, indeed, comprehensiveness seldom aids comprehension, particularly by those who are not engaged in this field. The practical advice for the identification and handling of the commoner allergens can be applied readily in practice.

A classification of the anti-histamine drugs based on various combinations with the active dimethylamino group is useful for therapeutic trials, and could be improved further by a clear classification of these drugs into sedative and stimulating, and long-acting and short-acting, and by advice on their combined use. The authors correctly point out that palliatives do not replace the "well-established," "cause and effect" investigation, and they might well have added a warning of the dangers of unexpected and unrecognised sedation by the anti-histamine drugs, which may endanger the patient and others. The long lists of trade names quoted for the various anti-histamine drugs illustrate a real source of confusion and the urgent need of a common name for each, to which the manufacturer's mark could be added.

The references have been judiciously chosen and do not hamper smooth reading, but there are unfortunate omissions of contributions from other countries—such as the extraction of a highly purified specific house-dust antigen, and its identification as a polypeptide-polysaccharide complex by Rimington et al., which has obvious advantages in diagnosis and treatment.

Congenital Heart Disease

HENNING GOTZSCHE. Copenhagen: Henning Gotzsche. 1952. Pp. 254. Kr. 25.

Scandinavian authors have produced a number of monographs on congenital heart-disease, and this work from Copenhagen is one of the most comprehensive.

It is based on 200 consecutive cases studied in the medical department of the university. A short historical introduction, a full clinical picture, and an account of detailed diagnostic methods, is accorded to each disorder. The radiographic features and electrocardiographic changes are carefully analysed, and well illustrated, and the more advanced investigations such as cardiac catheterisation, angiocardiography, and phonocardiography are discussed where necessary. The numerous tables and case-reports illustrate the care with which the book has been compiled, and the translator is also to be congratulated.

Diseases of the Esophagus

PHILIP THOREK, M.D., F.A.C.S., associate clinical professor of surgery, University of Illinois College of Medicine. Philadelphia and London: J. B. Lippincott. 1952. Pp. 140. 80s.

THE number of recently published monographs on surgery of the œsophagus show with what interest this subject is being pursued. In this concise and comprehensive work Dr. Thorek emphasises the pathological and surgical aspects. The half-tone illustrations and diagrams are of outstanding quality and of particular value to the surgeon. The sections on congenital defects and diverticula are especially good, but those on achalasia and hernia are less satisfactory. The points that probably require greater emphasis are the risk of regurgitation or reflux from stomach into œsophagus if the so-called sphincter mechanism is inefficient, and the ease with which the cardio-œsophageal junction can ascend into the thorax. Actually some of the operations described in relation to abnormalities in the lower œsophagus and diaphragm are so ornate in name and character as to merit their relegation to a museum, so as to make place for more simple and rational procedures. The treatment of carcinoma is well described and efficiently illustrated, but without reference to immediate or long-term results.

Annual Survey of Psycho-Analysis

A Comprehensive Survey of Current Psychoanalytic Theory and Practice. Vol. I. Editor: JOHN FROSCH, M.D., in collaboration with JACOB A. ARLOW, M.D., NATHANIEL ROSS, M.D., and SIDNEY TARACHOW, M.D. New York: International Universities Press. London: Allen & Unwin. 1953. Pp. 556. 75s.

THIS is the first of a projected annual issue, and it summarises the psycho-analytic literature for 1950. The definition of psycho-analytic is somewhat elastic, and though most of the publications reviewed are American the output of other countries has not been overlooked.

Some twelve authors present the various sections discussing history, critique, methodology, psycho-analytic studies in development, ego psychology, clinical studies, psycho-analysis and psychosomatic medicine, child analysis, psycho-analytic therapy (with four subsections), applied psycho-analysis (in six fields), and psycho-analytic training and practice. A 125-page chapter describes twelve of the more important psycho-analytic books published in 1950. Inevitably, there is some unevenness of style and treatment, and it was hardly to be expected that all the material should be new or profound; but to the practising analyst or the student the book should prove useful for reference.

Brain Surgeon

An Autobiography. WILLIAM SHARPE. London: Gollancz. 1953. Pp. 244. 16s.

THIS autobiography is full of clinical stories told with gusto and "all the tricks of salesmanship" that the author knows, and they are many.

Born of a Scots Presbyterian clergyman and brought up in the slum areas of Pittsburgh, Chicago, and Philadelphia, Dr. Sharpe won his way to Harvard and eventually to Harvey Cushing's clinic at Johns Hopkins where he learnt the craft of neurosurgery. At a comparatively early age he was appointed the first professor of surgery at the Harvard Medical School at Shanghai and his year of office brought much adventure and rich experience. He was invited to advise on the treatment of the President of China's eldest son, who was partially paralysed after a riding accident. In defiance of the opinions of the presidential physicians he operated successfully, and only when he had finished did he learn that, had he failed, his life might well have been taken by the patient's mother.

His main interests are in the relief of hydrocephalus and the occurrence of intracranial hæmorrhage in the newborn, which he believes is responsible for cerebral spastic paralysis.

Sir Cecil Wakeley describes Dr. Sharpe as one of the pioneers of neurosurgery. But, like that of most other pioneers, his point of view is not always the same as other people's; and his account of a demonstration laminectomy will spoil his book for many readers.

Progress in Ophthalmology and Otolaryngology

A Quadrennial Review. Vol. I. Editors: MEYER WIENER, M.D., A. EDWARD MAUMENEE, M.D., PERCY E. IRELAND, M.D., JOSEPH A. SULLIVAN, M.B. New York: Grune & Stratton. London: Heinemann Medical Books. 1952. Pp. 666. £5.

THIS book, containing 35 chapters on ophthalmology and 29 on otolaryngology, aims at covering the literature from 1946 to 1950. Opinions will differ on whether any useful purpose is thereby served. There are four excellent abstract journals in ophthalmology—two in English, one in French, and one in German. In addition, some ophthalmic monthlies carry abstract sections, while others carry critical review articles of recent work on particular subjects; and there is also a yearbook in ophthalmology and otolaryngology. Thus a quadrennial review necessarily tends to become a digest of digests. The standard reached by some of the chapters in this volume is high, but only when the writer has broken away from the stranglehold of abstracting papers published over a given period. Incongruously enough in a publication of this type, some chapters are in the nature of original communications. Most of the book, however, is parochial in outlook and takes little note of anything outside American journals.

The Wider World

THE HEALTH OF A TROPICAL PEOPLE

A Survey in Ceylon

H Cullumbine
M D , M Sc Sheff
LATE PROFESSOR OF PHYSIOLOGY AND PHARMACOLOGY,
UNIVERSITY OF CEYLON, COLOMBO

I METHODS OF ASSESSING HEALTH

Health strictly means wholeness, but, both for individuals and for communities, we need to specify the qualities in which wholeness is desirable The World Health Organisation in 1946 defined health as "a state of complete physical, mental and social well being and not merely the absence of disease or infirmity" This definition, while emphasising that many factors contribute to health, is not sufficiently precise for practical use The scientist in the field requires a definition in terms of qualities which he can measure accurately indeed, he has inevitably confined his assessment to factors which he can record accurately By thus limiting the number of health factors he studies, he has sacrificed comprehensiveness but he has achieved some accuracy of detail

The W H O definition implies at least three qualities in health—physical, mental, and social Physical health has been measured most often, though occasionally it has been studied in relation to some aspect of the gross environment—e g , economic status or sanitation Moreover, usually only some of its many aspects have been studied, the emphasis of the assessment varying with the interests of the observer For example, some workers have analysed the vital statistics of a community, others have assessed the nutritional status of the inhabitants, others have measured the physical development of the people, others, and more rarely, have examined the incidence of sickness

Efforts to standardise the methods for the assessment of health have been made from time to time, and lead to the development of the concept of health indices, about which a report was published by the health organisation of the League of Nations in 1939 This memorandum suggested that the health of a population should be measured by indices of (1) vitality and health, (2) environment, and (3) public-health activity

Standardisation of assessment is helpful in comparing the health of the same community at different times, or the health of different communities But the basis of assessment assumes that certain statistics are both available and reliable Moreover, much of the information demanded even if obtainable, is not applicable to primitive society for the health indices were designed to assess the health of the more advanced countries Thus in many countries of the world vital statistics may not be obtainable or if obtainable they may be of doubtful reliability or cover only major epidemic diseases, such as smallpox typhoid fever, cholera and plague Again even in the better-organised countries the morbidity statistics may relate only to hospital patients

Criteria

Any assessment of the diet of a community presupposes basic or minimal requirements for the various nutrients These requirements are still in dispute in the West, and some of them are probably different for the people of the East Thus the basal metabolic rate varies with climate, being less in the tropics than in temperate climates (Galvao 1948a and b) Moreover, the physique of most people in the East is different from that of people living in Europe or in North America, and so their daily energy requirements are different (Cullumbine 1950a) Because of their smaller stature the calcium requirement of Eastern people will probably be less too, and their calcium intake will vary further with their dietary pattern—e g , polished or unpolished rice—while allowance must be made for adaptation to adverse intakes (Cullumbine 1950b) The pattern of the diet may also influence the required intake of carotene (Hume and Krebs 1949) In other words, nutrient requirements cannot be standardised for the whole world, and local requirements must be established for each major community before the adequacy of diets can be judged

This may necessitate the selection and the study of a subgroup of the population who have shown adequate physical and physiological growth and development within the limits imposed by their environments and their heredity "Adequate" is here used in preference to 'optimal," since the optimal physical and physiological development is an ideal which has yet to be defined Thus, should we aim to achieve men six feet tall or should we be content with a race of five feet men? Is there any advantage in weighing 50 kg in Ceylon or 70 kg in Britain?

Not only has the optimal development to be defined but the significance of the observed range of variation of the physiological characters of the body is but little understood Can we say how the functional capacity of a man with a systolic blood pressure of 125 mm Hg and a blood hæmoglobin of 16 g per 100 ml differs from that of a man with a pressure of 115 mm and a hæmoglobin of 15 g?

Lacking a definition of optimal development, we need some yardstick for assessing not only the adequacy of diets but also the growth potential of the population This yardstick may be data obtained in a more prosperous and advanced country, though this is not always desirable since people may be ethnically different and may live in grossly dissimilar environments Here again we may have to select and study a subgroup of people within the same community, the selection is usually made from people who have a sufficient income (both monetary and in kind) to provide an adequate diet and who have sufficient education and intelligence to insist upon adequate housing, sanitation, and medical care

This yardstick population will itself vary in the factors to be measured, and should *not* be considered as necessarily a "*normal*" population In fact the concept of "normality" must be used with care As Sinclair (1949) has stated, its meaning may be different for different observers To a statistician it may indicate *that* a variate is within ± σ of the mean for a given population Such a definition may be useful when comparing subsections of a population, but it may not agree with the physiological concept of normal For example, it would class dental caries as being normal in an adult population (Sinclair 1949) Should "normality," therefore, be used to indicate merely the absence of signs and symptoms of disease? The pathologist and the clinician use such a standard and with justification, but it may be too crude a demarcation and ignore the finer gradations of function likely to be found in a large population Nor can "normality" be taken to signify perfection, since the definition of perfection will vary with the circumstances of the study The definition would then approach the physiologists' meaning of normal—viz , adequate function in the environment studied This meaning again requires classification—e g , of the environmental factors considered important, of the functions assessed, and of the qualification 'adequate"

Perhaps all these concepts of normality could be defined as the absence of the signs and symptoms of disease with adequate function under the conditions of study, and with all the measured varieties lying

THE LANCET

LONDON: SATURDAY, MAY 30, 1953

Negative or Positive?

In 1916 Lloyd George appointed a committee to consider means of securing permanent improvement in the relationship of employer and employee and of ensuring that industrial conditions affecting this relationship should be systematically and continuously reviewed. This committee recommended that each of the chief industries should have a representative joint body capable of dealing with matters affecting the welfare of the industry as a whole, and that every factory should have a works committee meeting regularly to deal with its own staff problems. The Whitley machinery devised for these purposes has since played an important part in negotiations between employers and employed not only in industry but in the Civil Service. The joint bodies or councils are named after the committee's chairman, J. H. Whitley, M.P., afterwards Speaker of the House of Commons.

The National Health Service is covered by nine Whitley Councils, each dealing with a particular type of staff, and one General Council.[1] The "management side" consists of officials of the Ministry of Health and representatives of regional hospital boards, boards of governors, executive councils, and local health authorities. The "staff side" consists of representatives of professional organisations and trade unions. The basic principle on which the councils were founded was that management and staff should reach agreement by joint consultation and negotiation, failing which they might agree to arbitration. The application of this principle to the hospital service is generally recognised as desirable; but the experience of the past few years has shown that the mechanism by which it is applied could be considerably improved, and some valuable suggestions to this end are made in a memorandum prepared by a group of hospital administrators.[2] In a service employing some 400,000 persons, whose salaries and wages account for 60% of the total expenditure, some form of central control over rates of pay is unavoidable; but the present system has an inflexibility which causes great difficulty at the periphery, where boards of governors and regional hospital boards have no power to vary national rates to suit local conditions, to reward meritorious services, or to bring exceptional experience to bear on an administrative problem. In some groups of workers, such as technicians in electrocardiography and electro-encephalography departments, unrealistically low rates of remuneration have been fixed and recruitment is consequently difficult. Admittedly the system has important advantages: employees know exactly where they stand, and the Ministry can maintain a large measure of control over the finances and man-power in the hospital services. But management committees and regional boards are increasingly at a disadvantage when they try to act as good employers and to compete with local industry. Moreover the ways in which uniformity can be wasteful have been evident for quite a long time.[3]

When taken over by the nation five years ago, the hospitals were at all stages of development, and judged by the criteria of business many of them fall far short of efficiency. Undoubtedly they still have much to learn from industry. But have they sufficient incentive to constant improvement? A new attitude of mind is badly needed to offset the depressing effects of Treasury strait-lacing, and we could wish that the Ministry of Health showed greater awareness of the need to study, on a research basis, the ways in which hospital administration could be improved. An active research programme, and a wider application of the lessons learnt from the best centres (which would come out very clearly if departmental costing were introduced), might well result in a 15–20% increase in efficiency without extra cost. The immediate need is not so much to establish special recognition of merit at lower levels —which can always be given by promotion—as to introduce exceptional men and women at exceptional salaries to assist in the development of a particular branch of the hospital service, such as catering, laundry, or records. As the hospital administrators' memorandum points out, some of the work they would do could fairly be regarded as research projects; and it might indeed even be financed out of endowment funds, thus circumventing Whitley designations. Again, incentive would be stimulated if exceptional merit could be recognised within the service by a system of monetary prizes awarded to those whose methods would clearly make a contribution to the National Health Service as a whole. The South West Metropolitan Regional Board award annually scholarships for medical research, and there is no reason why the same principle should not apply to the administrative staff; for we already have indices by which to assess their contribution. There is also the occasional individual—e.g., a surgical instrument technician—who has built up a highly specialised and extremely efficient department and whose particular contribution to his hospital is certainly not being properly rewarded by the national scale. It should be within the power of a regional board, when a really strong case has been made out, to sanction an increase in salary. In some aspects of hospital work, experiment is needed with different methods of pay—e.g., rates of pay based on piece-work in laundries.

As for the Whitley Councils themselves, the policy of stimulating maximum efficiency can be fully worked out only if all those serving on the councils are really familiar with the problems at the periphery. At present they are not. The Ministry's officials, living in the shadow of the Treasury, sometimes seem more concerned with outvoting other management representatives in the interests of financial stringency than in stimulating a good-employer policy. Insufficient liaison between these officials on the one hand, and the senior hospital officers or committee members on the other, means that the management side is not always fully briefed on within the limits ± σ of the mean of each variate. This approaches the type of definition which is often given to physical health, and, as I have said, it is usually physical health which has been assessed in health studies. But if a man is a creature of his environment, the study cannot be divorced from the social, economic, physical, and even political aspects of his surroundings. Otherwise the study becomes merely descriptive, and logical cause-and-effect relationships cannot be formulated.

---

[1] See *Lancet* 1948, i, 845.

[2] Multigraphed copies obtainable from Mr. J. D. Banks, Royal Cancer Hospital, Fulham Road, London, S.W.3.

[3] *Lancet*, 1949, ii, 201.

The assessment of physical health should include, therefore, at least

(1) A demographic study of the population.
(2) An analysis of the vital statistics for the population.
(3) An analysis of the prevalence of sickness within the population.
(4) A physical and physiological characterisation of the people.
(5) A dietary history of the population and its relationship to available food-supplies.
(6) A statement of the medical (and probably educational) facilities available to the population.
(7) A description of the physical, social, economic, and, possibly, political factors in the environment, at least in so far as these may effect the previous items (1–6 inclusive).

The Ceylon Inquiry

It is on these lines that, in the past four years, we have tried to evaluate the health of the people of Ceylon.

Ceylon is particularly well suited for a study of the health of a tropical people. It is a small island which can be adequately covered by one research group. Within this small space are to be found diverse ethnic, religious, educational, economic, and social characteristics which are broadly typical of Asia as a whole. There is, and has been for some years, a very comprehensive official computation of vital statistics. (The diagnosis of causes of death may be questioned but this will be discussed later.) In proportion to its population Ceylon also has, for Asia, a relatively large number of doctors trained in the Western system of medicine, and fairly good hospital services. The presence of a reliable system for the registration of vital statistics and the provision of a national medical service may be points of distinction from the rest of South-east Asia, but a study of the health experience in Ceylon may be a useful preliminary to an analysis of the health problems of this region.

The preliminary assessment of the health of the Ceylonese included

(1) A complete analysis of the recorded vital statistics for the past twelve years (Cullumbine 1951).
(2) A study of morbidity and disabling illness based on door-to-door interviewing of 17,946 households with 94,128 persons from all districts and communities in Ceylon (Cullumbine 1952).
(3) Anthropometric and physiological surveys involving about 10,000 subjects, with more detailed studies on smaller selected groups.
(4) A survey of the dietary habits of one in every thousand families in the total population (1400 families). This was done on a family basis and the food prepared for consumption by each family was weighed on seven consecutive days (Cullumbine 1951).
(5) An analysis of the food supplies, and of the medical facilities (Cullumbine 1949).

DEATH-RATES

Each of these studies had its own problems of measurement and of interpretation. Thus, though independent checks suggest that there is complete registration of births and deaths in Ceylon, the accuracy of the registered causes of death may be questioned. In selected urban areas the person appointed to be registrar is a doctor and he has a special responsibility for the certification of causes of death. But only about 15% of all deaths are registered with these medically qualified registrars, and a minority of all certifications are made by practitioners of Western medicine. The influence this has on the recorded causes of death is seen from the figures in the table, where the causes of infantile deaths in 1950 in the Kalutara Totamune have been separated into those registered with lay registrars and those registered with medical registrars.

THE PERCENTAGE DISTRIBUTION BY CAUSE OF INFANTILE DEATHS DURING 1950 IN THE KALUTARA TOTAMUNE

Cause of death	Lay registrar	Medical registrar
All causes	100 (364 cases)	100 (221 cases)
Convulsions	62·3	10·9
Prematurity	13·2	24·4
Infantile debility	1·6	20·4
Pneumonia	9·3	0·9
Bronchopneumonia	1·1	17·4
Bronchitis	—	2·3
Malnutrition, &c	2·7	5·4
Toxæmia (worms)	4·1	5·9
Enteritis and diarrhœa	2·2	5·9
Asphyxia neonatorum	—	2·3
Icterus neonatorum	—	0·9
Other causes	3·4	3·3

The two lists suggest that we are dealing with two distinct populations so widely do the recorded causes of death differ. Actually each list applies to people living in the same area, although the medical registrar's district is slightly less rural than the lay registrar's district. Because of the uncertainty about individual causes of death, groups of major diseases rather than specific causes have been considered in the analysis of the vital statistics. It must be remembered, however, that it is usually agreed that Ceylon's vital statistics are more accurate than those of the rest of South east Asia.

SICKNESS-RATES

The study of morbidity in a community is more difficult than the study of mortality. As deaths have to be registered by law, their number can be readily determined; but the incidence of illnesses is a matter for speculation. The cause of death has also to be registered, so that the certifier is faced with the necessity of making a diagnosis. The diagnosis may be wrong, but the onus of officially committing a professional opinion to paper induces a little extra thought and caution and at least provokes some degree of wisdom after the event. An illness, on the other hand, may never be diagnosed, though the patient, his friends, and his medical advisers are usually stimulated to tentative fancies.

As a rule the only morbidity statistics available which possess any degree of accuracy in diagnosis are those from hospitals. These hospital figures do not necessarily bear any relation to the actual incidence of disease or to the total deaths. As a rule, the cases admitted to hospital are those with a serious prognosis or which require skilled or technical treatment. The wishes of the patient and the doctor, the availability of hospital beds, the degree of safety involved in moving a sick person, and many other factors will influence admission. The hospital statistics will indicate, however, the incidence of the major incapacitating diseases in a community and, remembering their limitations, should repay study.

Hospital statistics in Ceylon do not give the age, the normal residence, and occupation, nor other socio-economic details about the patient. It did seem desirable, therefore, to attempt to fill this deficiency by a morbidity survey.

The planning of such a survey is hampered at the outset by the lack of an agreed definition of sickness. Downs and Collins (1940) have described sickness as a "disturbance of health"; but this, as Stocks (1947) has maintained, involves the "mystical word health" for which, again, an agreed definition is still needed. At present it is probably better to give an accurate description of the type of information obtained rather than a the merits of the different cases submitted to the councils. A more positive policy on the management side might well lead to less arbitration and might speed up the work: when it may take eighteen months to get a ruling from a council on a small but important point, much frustration is felt at the periphery. The hospital administrators' memorandum makes out a strong case, too, for strengthening the Staffing Division of the Ministry of Health. This Staffing Division has, in fact, been formed only recently, and we trust that it will be able to ensure not only adequate briefing on individual cases but also the continuous review of policies for recruitment and training and of the effect of existing scales. At present the Ministry, through the Whitley Councils, has a negative rather than a positive influence, and the service thereby suffers. A proportion of work which should be done by the Staffing Division is already done by the independent foundations, the King's Fund and the Nuffield Foundation; but great scope remains, particularly if such a division could be built up with a strong statistical and research section.

The Whitley equivalent of the works council, the joint consultative staff committee, has now been formed in all hospitals, and they are improving the sense of cohesion which is so desirable in any large community. There can be nothing more frustrating than being unable to put forward constructive criticism—a situation commonly found unless there is an alternative to a difficult foreman or departmental head—and such committees can ensure adequate attention to reasonable facilities—e.g., catering, cloakrooms, and rest rooms—which have always existed for the professional staff. These committees undoubtedly make a positive contribution to local morale and thereby improve efficiency, and it seems a pity that the medical staff have been excluded from their constitution. The professional reputation of the hospital and the efficiency of medical care depend largely on the senior medical staff, and it is particularly unfortunate that their medical committees should not have any statutory recognition. Indeed, a curious situation has now arisen whereby management committee members or governors come officially into contact with, and get to know, technical and manual staff, but have no such official opportunity for getting to know senior medical staff.

Angiocardiography

IN 1929 FORSSMANN introduced a ureteric catheter into his own arm, passed it into his heart, and injected 'Uroselectan' into his right auricle; but it was not until 1939 that ROBB and STEINBERG described a relatively safe and practical method of displaying the heart and pulmonary vessels. With this method radiologists had to take a series of films in rapid succession—an exciting challenge to their technique. Not all workers, however, felt the need for multiple films: and many of the pioneer investigations by ROBB et al. were made with only two films, taken at intervals determined by the circulation-time. The usual contrast medium is diodone (70%) and in the conscious patient this produces some very unpleasant sensations.[1] These can be minimised by premedication and forewarning; but not every patient is willing to undergo a second injection, and a medium less toxic and more radio-opaque is greatly needed. As part of the price of this investigation, there has been a small but steady number of deaths,[2] mainly among severely handicapped children.

The period of initial exploration is over, and few abnormalities of the chest have not been investigated by this method. Sometimes the information gained has proved important, but often the method has done no more than dramatically portray the obvious or confirm a probability. Occasionally, however, angiocardiography provides essential information that cannot be procured by any other means. In the investigation of diseases of the lung, it has so far proved disappointing.[3] There seemed no reason why neoplasms of the lung should not alter the pulmonary vascular pattern in some characteristic way, as do neoplasms of the brain. But this is not so; the tumours are not to be seen, and the most that can be expected is evidence of some displacement of the vessels or of involvement of the pulmonary artery or venæ cavæ. So far as the lung is concerned, it is only in investigation of possible vascular abnormalities that angiocardiography is justified. Arteriovenous fistulæ can be beautifully demonstrated, but the diagnosis is usually made by clinical examination and can often be confirmed by plain radiography and tomography. In this condition the real value of angiography is to make sure that the lesions are not multiple, and that smaller and less obvious foci are not being overlooked. Angiography may be helpful in cases of so-called unilateral emphysema. With plain radiography a very similar appearance can be produced by thrombosis or obstruction of one of the main pulmonary arteries, but an angiogram should at once separate the two conditions. Perhaps the most important use of angiocardiography is in the investigation of mediastinal tumours, when it can usually be relied on to reveal aneurysms of the aorta or pulmonary artery, or to delineate an abnormal course of one of the great vessels or their branches. Occasionally the method may be misleading, as where a clot has formed in an aneurysm, or where the opening into a saccular expansion is too small for much contrast medium to enter: but unless plain films and screening show the tumour clearly separated from the aorta and pulmonary artery, an angiogram is justified. No reliance should be placed on kymography, which many workers have found most deceptive.

In acquired heart-disease angiocardiography is still on trial.[3] In syphilitic aortitis enlargement and irregularity of the calibre of the aorta can be shown early,[4] and the diagnosis of pericardial effusion may sometimes be clinched by showing the extent to which the cardiac outline extends beyond the chambers of the heart.[3] In acquired valvular disease of the heart the method has displayed the enlarged chambers; but so far it has not been possible to demonstrate the valves, and attention has centred on the secondary effects in the lung fields.[5] Care, however, is needed precise, but debatable, definition of illness (Bransby 1948)

Information on sickness can be obtained either from doctors or lay people The first source should give more accurate information about the causes of sickness, but it limits the survey to illnesses treated by doctors and to people who seek medical aid If lay people are questioned then a more representative sample of the population will be obtained, but the reported causes of sickness will be less accurate, and the information will depend on the memory of the individual and his psychological attitude towards illness

Despite these difficulties a morbidity survey provides data on the incidence and social distribution of sickness which are necessary for the evaluation of the health of the people and for the planning of health services

The survey in Ceylon was designed to answer two questions

(1) How many of the working population were unable to attend their regular duties on the day of the survey because of disablement ?

(2) How many people had been ill during the past year ?

We realised that a year is a long time to expect people to remember their illnesses, but information on this point, however crude, was needed for other purposes The investigation of disablement was made as objective as possible in order to increase the accuracy of recording for the lay interviewers

ANTHROPOMETRIC AND PHYSIOLOGICAL SURVEYS

The anthropometric and the physiological surveys collected data on the physical and physiological growth of the Ceylonese from all districts, economic groups, ethnic groups, and communities Exercise tests were also performed by many of the subjects and, from all these collected data, correlations were derived between (1) each physiological character measured and the exercise performance indices, (2) various anthropometric indices and the exercise indices, and (3) each physiological character and certain anthropometric indices

The nutritional data were related as far as possible to "standards" obtained from selected groups of Ceylonese Thus, from studies of basal metabolic rates, calorie requirements were computed for various age groups Mineral and nitrogen balance studies gave evidence for basal intakes of these nutrients Investigations of the foodstuffs consumed by middle class schoolboys indicated what and how much healthy boys were eating

It was possible to analyse all this physical, physiological, mortality, morbidity, and dietary information according to age, sex, community, district of residence, family income, &c , and thus to compose a coherent picture of the health of the Ceylonese within their social environment It would be more difficult to do this in a larger and more complex society, but it could be attempted in other small, selected regions Before health problems can be solved these problems must first be described and their magnitude defined In many areas of the world the mortality, morbidity, and nutritional data are fragmentary, but active health programmes are being applied on this incomplete information Investigation should precede correction

Special Articles

THE WORLD'S FOOD-SUPPLY

On April 22 the nutrition panel of the food group of the Society of Chemical Industry held the final meeting of the series[1] on Food and the Future The subject under discussion was Synthetic Potentialities

Mr W F J **CUTHBERTSON**, PH D (Glaxo Laboratories Ltd), discussed the general possibilities of supplementing our food supply by synthetic substances The direct synthesis of bulk foods—the fats, carbohydrates, and amino acids—was not likely to play a material part The process would require enormous quantities of energy, and if the problem were to be projected into the speculative future, our reserves of oil and coal, and even atomic energy, must be considered as strictly limited and diminishing assets On the other hand, chemical transformation of natural products could perhaps lead to the production of large quantities of food from inedible crop residues The greater part of our plant production was composed of polysaccharides and lignin, and little energy would be required to transform these into carbohydrates or fats The potentialities of this method were shown by the industrial production of dextrose from sawdust, which was carried out with reasonable efficiency

Synthetic chemistry was far more likely to play its part in the preparation of essential substances which were required in relatively small amounts Already all the vitamins had been synthesised, and most of them were produced on the factory scale for supplementing the human diet Although few of the amino acids could yet be synthesised in bulk, the two in which foods were so often deficient, methionine and lysine, were fortunately being produced on a large scale The value of supplementing the human diet with synthetic vitamins had been well illustrated in the Philippine Islands, where fortification of polished rice with synthetic thiamine had resulted in the abolition of beriberi

In animal nutrition these synthetic substances offered great possibilities We knew most, if not quite all of the various food factors required to maintain health and rapid and economic growth of our farm animals Unfortunately high-yielding food crops all showed some degree of deficiency of one or more of the essential food factors, thus, wheat lacked vitamin D and ascorbic acid, and maize was poor in vitamin B$_{12}$ and tryptophan The procedure had been to grow higher-quality crops of lower yield to supplement these deficient foods or to use costly materials, now difficult to obtain for this purpose, such as milk, fish meal, or meat meal Now that synthetic additives were available, it was possible to grow the most efficient crops, in terms of calories per acre, and to raise the quality of the food with these supplements Already, in the U S A , synthetic riboflavine, at the rate of 2 g per ton of diet, had replaced 20–100 lb of dried milk or whey solids, vitamin B$_{12}$, produced by fermentation, had replaced part of the requirements of milk and fish products, maize and soya were supplemented with synthetic methionine, wheat and cotton seed were fortified with lysine, and synthetic vitamins and choline were added to the diet As a result it was now possible to rear chickens to 4 lb weight in ten weeks on a total food intake of 10–15 lb, instead of twelve or thirteen weeks on 16–20 lb of food These supplements might be added directly to human food A completely vegetarian diet would be far more economical than our usual diet, but we did not yet know whether it would be adequate When all the food factors had been identified, the synthetic chemist might be able to make a wholly vegetarian diet which was fully adequate in drawing conclusions about the state of the vessels or the pulmonary blood-pressure from isolated snapshots of the lungs. The method has been much used in congenital cyanotic heart-disease. GOODWIN et al.[5] point out that even here *it is only an auxiliary* investigation which should not be used indiscriminately in all cases. Not every blue child need be subjected to angiocardiography and safe cases must be selected wit. [illegible] whether a child liable to syncopal attacks should ever be submitted to this manœuvre, for the profound fall in blood-pressure always induced by the injection may easily prove fatal.[6] The investigation can be useful, not only for diagnosis (commonly the diagnosis has already been made) but for the information it gives about the anatomical disposition of vessels available for anastomosis, and also about any additional defects and complications hitherto unsuspected. Nevertheless angiocardiography can be positively misleading, and its evidence should seldom be preferred to the findings from cardiac catheterisation. It may be no easier to assess the pulmonary vascularity when the vessels are full of contrast medium than with plain radiography, and on occasion the contrast medium appears to stream past one pulmonary artery and thus gives a false impression of abnormality. This investigation is most likely to be helpful in distinguishing pulmonary stenosis plus an atrial septal defect from a simple Fallot's tetrad; in demonstrating the abnormal origins of the great vessels in cases of transposition; and in showing whether any pulmonary arteries are present in cases of pulmonary and tricuspid atresia. *Angiocardiography plays no part in the diagnosis of* coarctation of the aorta; but by no other means can the narrowing be so well displayed, and most surgeons now like to see an angiogram before operating. If the aorta is not shown well enough by a venous angiocardiogram, the contrast medium may be injected through a catheter introduced into the aorta through the right radial or brachial artery; and a similar selective angiogram can be obtained with a catheter in the right ventricle, in an attempt to throw more light on an infundibular or valvular stenosis. These methods are, however, perhaps especially risky.

So much time and money has been invested in angiocardiography that undue emphasis may have been laid on the information that it yields; and one suspects that occasionally the patient may have been sacrificed to the machine. The next technical advance will almost certainly come through screen cinematography, and has been brought much nearer by the introduction of a practical screen-image intensifier. This apparatus can already increase the brightness of the screen a thousandfold, and it should not be long before ciné films can be safely taken without risk to the patient of overexposure.

Annotations

GENESIS OF GLOMERULONEPHRITIS

HÆMOLYTIC streptococci were once feared for their invasiveness: erysipelas or lymphangitis could cause grave anxiety, but now these respond rapidly to chemotherapy, and death from septicæmia is rare. But streptococci are still dangerous because of the peculiar sterile inflammations they sometimes provoke—namely, glomerulonephritis and rheumatic carditis. These disorders both involve tissues not invaded by the organisms and follow rather than accompany the infection; both may continue to advance long after the infection has gone. The relation of the infection to these sterile inflammations is mysterious: one naturally looks for some mechanism common to both, but there are a number of differences which restrain generalisation. For example, complement is raised or normal in rheumatism but is lowered in acute nephritis,[1] and there are some interesting epidemiological contrasts.[2] The incidence of acute rheumatism varies with class and climate, but within a given community it complicates a fairly steady fraction of streptococcal infections. It is common for different members of a family to be affected at different times, and only too common for one patient to have repeated attacks. Acute glomerulonephritis does not show the same geographical variations, but its incidence in outbreaks of streptococcal infections varies greatly even in one locality, sometimes being so high that it appears itself as an epidemic disorder. Apart from episodes of this type the relatives of patients are not especially at risk, and after complete recovery second attacks are rare.

An explanation of these differences is suggested by recent bacteriological studies.[3–5] Some, but by no means all, group-A streptococci may be placed in distinct serological types, of which about 50 have been described. It has been found that the frequency of these types in association with acute nephritis does not correspond at all with their general frequency: a great excess of type 12 has been found and a smaller excess of a few other types. On the other hand, outbreaks due to type-12 are not always followed by a high incidence of nephritis, so the existence of a factor correlated with, but separable from, the type specificity is suggested.

Typing is an expert matter. The importance of these findings is not in any promise of early help in controlling the disease but in the insight they give into its genesis. The suggestion is that a peculiarity of the streptococcus is important, and perhaps necessary, for the development of nephritis after infection; and this would explain the epidemiological features. The different behaviour of acute rheumatism suggests that in this disease peculiarity of the host is more important than that of the streptococci.

GROWTH HORMONE AND CHRONIC ARTHRITIS

THE explanation of some forms of chronic arthritis as the result of overproduction or imbalance of adrenal cortical hormones arises from Selye's conception that a disordered pituitary-adrenal response to stress is largely responsible for this type of disease. The ability of cortisone, an adrenal glucocorticoid, to ameliorate arthritic conditions, both clinically and experimentally, supports this view, for hydrocortisone is a natural product of the adrenal cortex, its release is stimulated by pituitary corticotrophin, and its action may be interpreted as a means of redressing the hormonal balance. Selye's work,[6] and that of others,[7 8] has shown that mineralocorticoids, such as deoxycortone, can exert, experimentally, an opposite effect to that of

[8] Hughes, C. D., Swenson, M. J., Underbjerg, G. K. L., Hughes, J.S. *Science*, 1952, 116, 252.

Mr P N **Williams** (Lever Bros and Unilever, Ltd) discussed the possibilities of "synthetic fats" These were produced on an industrial scale during the war in Germany, but there were many drawbacks to their use Synthetic fats contained the unnatural odd numbered carbon chain fatty acids, and it had been suggested that these were harmful There was, however, good evidence that this was not so But other criticisms were valid synthetic fats contained branched-chain fatty acids which were toxic and resulted in restriction of growth, and they also contained dibasic acids which led to the excretion of dibasic acids in the urine, which was said to harm the kidneys Both of these toxic substances could be removed from the fat, but only at high cost

There was certainly insufficient evidence from which to argue for the consumption of synthetic fats by man The only nutritional tests which had been made were carried out in Germany, and the results were conflicting Apart from this, Mr Williams was very pessimistic about the possibilities of synthetic fats making a reasonable addition to our food-supply because of the cost and the quantities required The German process reached the stage of industrial production, but the output was only 2000 tons per year, compared with the world consumption of 18,500,000 tons of natural oils

Fats produced by moulds and yeast were more likely to be of value They could be grown on waste carbohydrate, and the fats produced should be nutritionally similar to vegetable fats, although they had not yet been tested

DISCUSSION

Mr N W **Pirie**, F R S, questioned the value of estimates of the life of our fuel reserves He suggested that the supplementation of foods by synthetic materials was a catalytic process, catalysing the efficiency with which foods were used

Mr A L **Bacharach** pointed out that synthesis might be an indirect means of supplementing the world's food-supplies, depending upon how much edible oil was at present used for industrial purposes He criticised the pessimism about synthetic fats because of their cost by pointing out that increasing demands for vegetable oils, together with the rising standards of living in tropical countries, might well raise the price of natural fats, while technological improvements might reduce the cost of synthetic fat

Mr H **Greene** PH D, said that the demand for a higher standard of living among the inhabitants of underdeveloped countries caused a demand for books, films, and textiles, and only a small demand for food, which could usually be met with no great difficulty

Mr H **Pritchard** said that unnatural fatty acids gave rise to toxic end-products of metabolism, such as oxalic acid, and in the case of elm fat, sebacic acid

Mr H **Moult** suggested that fat supplies could be eked out by the addition of small amounts of linseed and castor oils He said that the Indian government was seriously considering the use of ground-nut oil as tractor fuel

After the discussion, Mr **Norman Wright**, D SC (Ministry of Food), summarised the four meetings The unconventional foods, with the exception of leaf protein, had been disappointing In particular, food yeast which was being produced commercially, was finding little favour as human food Far more investigation into their possibilities was required and they must be regarded as long term projects For example, chlorella culture might become essential in an emergency, but its cost must be calculated in terms of human activity Even after the technical production problems had been solved, there still remained the problem of converting a structureless and insipid material into a palatable food

The progress in conventional methods was also disappointing Several speakers had emphasised the need for planning, but there were inadequate data For example, we did not know the possibilities of increasing areas under cultivation and yields of crops, we did not even know the potentially cultivable area in the world Fawcett had estimated that climatically there were 5 acres of land available per head, of which one third was cultivated, but we had no knowledge of the extent to which this area could be increased

Dr Wright concluded by saying that the solution of the problem needed determined and imaginative leadership, together with the intelligent application of the available knowledge by the rank and file of the world's agricultural people Science could only give an aid, it rested with man himself to determine what use he made of it

---

TERMS OF SERVICE OF HOSPITAL STAFFS

The terms of service of hospital staffs were discussed at a meeting of Committee B of the Medical Whitley Council on May 12

CLAIM FOR A REVIEW

Ten months ago the staff side notified the management side of Committee B of its intention to seek a review of the remuneration of hospital medical staffs, in order to secure full and proper implementation of the recommendations of the Spens report on the remuneration of consultants

Discussions were held with the management side in October and again in January, and the staff side has submitted at least three comprehensive memoranda on the subject So far the management side has not replied to the representations put forward and has not indicated its attitude towards the claim Nearly four months ago the staff side submitted a memorandum to the management side in reply to certain questions and referring to a number of important principles arising out of the Spens report

At the meeting on May 12 the staff side learnt that the management side are still not in a position to enter into discussions A very strong protest was made at the continued delay on the part of the management side, and an assurance was given that an early meeting would be held—in probably a month's time—when the management side's reply would be available

ALLOWANCES FOR WHOLE-TIME OFFICERS

During the past two years the staff side has repeatedly urged the management side to reconsider the allowances paid to whole-time members of hospital staffs, and to relate them to the clear intentions of the Spens Committee These discussions have covered such items as mileage allowances, rental for telephone, membership of learned societies, and allowances towards the expenses incurred in the purchase of textbooks and professional journals The management side has so far declined to make any amendments to the existing terms of service

On May 12 these matters, and also the question of domiciliary consultations, were raised again, and the case was presented by representatives of whole-time consultants specially coopted to the staff side, three of whom were appointed by the Association of Whole-time Consultants The management side pointed out that all the points made by the deputation of whole time officers had already been put to them very forcibly by the staff side itself They indicated, however, that they did not feel able to accede to any request which would place whole time members of medical staffs in a privileged position and on a different basis from other whole-time members of hospital staffs They therefore held out little hope for any concession in regard to mileage allowances and telephone rentals, but they agreed to consider whether anything could be done to assist whole-time cortisone; for example, in rats they aggravate both scorbutic arthritis and formalin periarthritis in animals sensitised to their action by unilateral nephrectomy and an increased salt intake. This type of experimental "adaptation disease" can only be produced when the adrenal cortex is intact. In further experiments,[9] Selye showed that lyophilised anterior pituitary increased the sensitivity of the rat to the effects of mineralocorticoids, and he attributed this to a direct sensitisation of the tissues. He identified the pituitary factor with growth hormone and pointed out the analogy with A.C.T.H. and cortisone. An explanation of chronic arthritis along these lines, therefore, supposes the existence of an intact pituitary-adrenal mechanism.

Reinhardt and Li[10] have lately reported results which suggest a different significance of pituitary hormones in experimental arthritis. They found that administration of growth hormone over a period of several months to adrenalectomised and ovariectomised guineapigs (fed on 1% NaCl and stock diet) produced definite chronic arthritis with bony changes, and 1 of 10 normal animals given growth hormone also showed arthritic lesions; but none of the untreated normal controls were affected. These results suggest that growth hormone itself may be directly responsible for chronic arthritis, for they were obtained independently of the adrenal gland and its hormones. They also suggest that cortisone exerts its anti-arthritic effects by suppressing secretion of growth hormone, or, as Selye suggested, by antagonising its local effects in the tissues. Reinhardt and Li make it clear that they have not so far excluded non-specific sensitisation to pituitary hormone as a possible explanation of their results. It has already been suggested[11] that insufficient heed was given to the possible effects of hypersensitivity in interpreting Selye's experiments. These latest results in this complex subject both amplify and challenge our present views on the place of the adrenal cortex in the development of arthritis.

ALLERGY TO ACRYLIC RESINS

A CASE recently heard by a tribunal in Edinburgh[12] raises a matter of interest and importance to doctors and dentists—allergy to acrylic resins. The facts were these. A patient who had worn an upper denture for some eight years without trouble began to have pain and swelling in the mouth within two days of having the denture relined. A doctor whom she consulted told her that her mouth might always remain sensitive, and the appeal was then brought, not against the dentist concerned, but against Edinburgh Executive Council, which had refused any grant towards charges incurred by the patient for private dental treatment. During the hearing it was stated that 1 in about 5000 patients was allergic to acrylic resins.

The cause of such allergy is still undetermined. In the past, soreness of the mouth developed with vulcanite dentures; but this was almost certainly due to small amounts of mercury salts in the red or pink colouring-matter of the rubber. It has been suggested that with acrylic resins it is not the polymethyl methacrylate itself that causes the trouble, but rather the presence of such plasticisers as dibutyl phthalate which are added to improve its working properties. Early in the late war there were several instances of dermatitis under the side-pieces of spectacles, and this was traced to the plasticiser used during manufacture; but there is little evidence that the same cause holds with denture materials. At present the allergic reaction is usually held to be caused by traces of unpolymerised monomer in the finished denture. Evidence for this view is rather slight; but these unpleasant reactions have commonly been observed after the use of auto-polymerising resins for relining, and it is quite possible that the Edinburgh case comes into this category. When these auto-polymerising resins are used for conservative dentistry, there is often a transient, and usually harmless, hyperæmia of the tooth-pulp. Fortunately, a patient who cannot tolerate acrylic resin alone will be quite happy with a vulcanite denture faced with acrylic resin, or even an acrylic-resin denture with a stainless-steel lining. A reaction seems to arise only when there is actual contact with the palate or the mucosa over the alveolar ridge.

Meanwhile, the dermatologist faces a pretty problem in the patient who must wear rubber gloves in order to avoid severe dermatitis when handling monomeric and polymeric acrylic, and yet can wear an acrylic-resin denture without trouble.

COLICINES AND BACTERIOPHAGES

THAT certain strains of *Bacterium coli* and other enterobacteriaceæ can produce antibiotic substances or "colicines" active against other coliform organisms, has been known since 1925.[1] The colicines are proteins or polypeptides, and their production and antibiotic action resemble in many ways those of bacteriophages. The relation between these two types of biological agents has been studied extensively in the last few years by Fredericq[2] and his colleagues in Belgium, and by workers in Lwoff's laboratory at the Pasteur Institute.[3]

Bacteriophages differ from colicines in that they possess both desoxyribonucleic acid (D.N.A.) and protein portions, and reproduce themselves in the sensitive bacteria they kill. Both phages and colicines can be characterised by the spectrum of their activity on different bacterial strains; and, just as plaque formation may differentiate one phage from another, so the type of clearing produced on a plate by a colicine may be a characteristic of it. Resistance or susceptibility of bacteria to phage and colicine action depends on the absence or presence of specific cell receptors to which these agents can attach themselves. In some cases the same receptor is used by a phage and a colicine; and a mutant, becoming resistant to a certain phage through loss of this receptor, will also become resistant to a colicine at the same time.

Both colicines and temperate phages are produced in bacteria—in colicinogenic and in lysogenic strains, which are themselves resistant to the agents they release. Some of these strains can be made to produce colicines or phages in large amounts by irradiation with ultraviolet light or treatment with certain mutagens and carcinogens. In both cases, during the latent period before the release of these agents residual growth takes place, respiration continues to increase, ribonucleic-acid metabolism proceeds, and the formation of adaptive enzymes or virulent phage can take place in the bacteria. In induced colicinogenic strains, however, D.N.A. production continues, while in lysogenic strains this is blocked for the first part of the period, perhaps because of the presence of induced phage D.N.A.

If in their production colicines simulate temperate phages, in their action on sensitive bacteria they imitate virulent ones. Only one particle of each is necessary for their lethal action on bacteria, and their adsorption constants are of the same order. Whereas, however, in bacteria infected with a virulent phage those processes necessary for phage reproduction continue, colicines inhibit all synthetic activities.

Although in many ways colicines and phages resemble one another no serological relationship has yet been proved, perhaps because colicines are poor antigens;

GENERAL MEDICAL COUNCIL

SESSION MAY 19–20

THE General Medical Council met on May 19 and 20, and its session was followed by the sittings of the Medical Disciplinary Committee

PRESIDENTIAL ADDRESS

Prof **DAVID CAMPBELL** said that the *British Pharmacopœia, 1953*, published in March, will become official from Sept 1 Among the many changes in this 8th edition is the abandonment of Latin in the main titles of the monographs—a break in the tradition established in 1535 when Valerius Cordus at the early age of 27 published his *Dispensatorium* in the city of Nuremberg, the first pharmacopœia to have civil authority "But the break was inevitable The ever-increasing number of new drugs made it extremely difficult to coin suitable Latin titles for new monographs without running the risk of making confusion worse confounded"

Referring to the rules made in 1945 for courses of study and examinations for diplomas in public health, the President said that these were to a certain extent experimental, being designed to meet the changing circumstances of the public health services at that time They provided for a preliminary course, after which a certificate in public health may be granted, and a final course, designed especially for future medical officers of health, followed by an examination open only to holders of the certificate

"Since these rules were adopted, great changes have occurred in the conditions of medical practice The National Health Service, introduced five years ago, has altered considerably the scope of the work of medical officers of health, while the institution within the last six months of a compulsory year of house officer service will affect practitioners in the early years of their careers It is not a matter for surprise, therefore, that those most directly concerned are disposed to think that the rules made in 1945 might profitably be reviewed at this stage in the light of the changed conditions and the experience now available"

Jan 1, 1953, was the appointed day on which the provisions of the Medical Act, 1950, which require proof of special experience as a condition of full registration, were put into effect "In anticipation of the introduction of the new conditions," said the President, "more than a thousand practitioners holding Commonwealth diplomas applied to be registered, and the great majority were able to obtain registration before the appointed day" The total number of names on one register at the beginning of this year was 83,914 Twenty years ago the number was 56,741 "The striking increase during the past two decades must mean that many more avenues of employment have been opened up to duly qualified and registered practitioners of medicine That is highly satisfactory But it prompts the question as to whether this is likely to continue, and whether there will be a limiting factor to a further increase"

DISCIPLINARY CASE

The council completed its last penal case

This was the case of *Garden Hepburn Swapp*, M B Aberd (1928), registered as of 8, Bath Street, Stonehaven, Kincardineshire, against whom the council had found proved convictions relating to drunkenness when in charge of a motor car Judgment had been postponed until the present session In view of the testimonials produced by Dr Swapp, the Registrar was not directed to erase his name from the Register

The **PRESIDENT** recalled that during the last two years the council had had, under the Medical Act, 1950, to complete cases which it had already begun In future all disciplinary business would be a matter for the Medical Disciplinary Committee

BUSINESS OF THE COUNCIL

At its meeting last November the council asked the Executive Committee to report on the mode of election of the Medical Disciplinary Committee, to ensure that as far as possible all members of the council took part in its work

The **PRESIDENT**, presenting the report of the Executive Committee, explained that it agreed with the opinion expressed by several members of the council that the present method tended to result in the re election of existing members It regarded the work of such importance that as far as possible all members should be afforded an opportunity of serving on the Medical Disciplinary Committee or the Penal Cases Committee The Executive Committee recommended in regard to the former that there should be a rota with a certain number of retiring members deemed ineligible for re election for a period of one year Explaining the proposed method, the President remarked that it was important to ensure substantial continuity, and he revealed that the Medical Disciplinary Committee had given up the practice of postponing judgment for two years, it now postponed judgment for six months or one year

The council approved the proposals for the new form of election, which is to come into operation next year The Executive Committee is to consider and report on a similar arrangement for the election of the Penal Cases Committee

Dr **H GUY DAIN**, presenting the report of the Pharmacopœia Committee, stated that 17,453 copies of the *British Pharmacopœia, 1953*, which comes into force on Sept 1, had already been sold

The problem of approved names was, he said, a very difficult one When a new substance was put on the market the person who made it chose a name The American Medical Association and the World Health Organisation might or might not choose the same name, and the Pharmacopœia Commission had to choose a name for a substance which had already got a name It was necessary to find appropriate names for the "flood" of new substances From the *Pharmacopœia* point of view, a name was wanted which did not convey any suggestion of the use of the substance The Pharmacopœia Commission had given the Committee their ideas as to the way in which the names were chosen, they endeavoured to keep them as short as possible Substances were submitted to the Pharmacopœia Commission to be named, and names were attached to them as soon as possible This applied to substances which might never come into use or get into the *Pharmacopœia*

The selection committee had learnt with much pleasure that Prof D M Dunlop, the chairman of the Pharmacopœia Commission, 1948–53, would be prepared to continue his services as chairman The council confirmed the appointment, and also the appointment of the members of the new commission

Dr **J P HEDLEY**, the senior treasurer, referred to the satisfactory financial position of the council at the end of the year This was mainly due to the large number of Commonwealth registrations of persons becoming registered before new regulations for the intern year came into operation For 1952 the council had a total excess of income over expenditure of £25,271

DIPLOMAS AND CERTIFICATES IN PUBLIC HEALTH

The council considered the annual returns of the results of examinations held in 1952 for certificates in public health and diplomas and degrees in sanitary science, public health, or State medicine, and information received from licensing bodies Members had had circulated a memorandum expressing the personal views of Prof Walter Schlapp and Dr Fraser Brockington, professor of public health at Manchester

The **PRESIDENT** observed that in general the numbers of those who took the certificate in public health in 1952 but antibacterial serum protects cells from the lethal action of both. In certain cases phages can kill bacteria without multiplying in them, and phage "ghosts" deprived of their D.N.A. by "osmotic shock"[4] can also destroy cells in a manner very similar to that of colicines. At least one strain produces both a bacteriophage and a colicine.

Perhaps when the D.N.A. of a phage enters a bacterial cell[5] it takes over the colicine-synthesising mechanism and diverts it for the production of its own protein coat. Whatever the exact relation between these agents, both are obviously involved in reactions which are proceeding along very similar lines, although self-reproducing units are formed only by bacteriophages.

TREPONEMAL IMMOBILISATION TEST

At present the treponemal immobilisation test for syphilis is being investigated at some 26 laboratories throughout the world.[6] This test, described by Nelson[7] in 1949, rests on the immobilisation of *Treponema pallidum*, in a special medium to ensure its survival when exposed to syphilitic serum and complement. The test is receiving especially close attention in France.[8] [9]

Touraine[9] takes the view that in primary and secondary syphilis the clinical diagnosis can be confirmed much more easily and quickly by dark-ground examination and the usual serum tests—a contention that is supported by the figures of other workers. In the early stages of the disease these serum tests become positive before the immobilisation test, but in the later stages the immobilisation test discloses latent syphilis in cases where the serum tests give no clue: in congenital and latent syphilis the immobilisation test is always positive. In tertiary mucocutaneous syphilis this test is positive in 98–100% of cases, compared with 48% for serum tests; and the proportions are much the same for late visceral syphilis. As regards neurosyphilis, in tabes dorsalis the immobilisation test is much the most useful; in one series cited by Touraine, it was positive in 33 out of 35 cases, in 18 of which serum tests were negative or doubtful.

Apparently the immobilisation test is specific; when it is positive—provided the other treponemal diseases, such as yaws and pinta bejel, have been excluded—syphilis can be diagnosed with some confidence. Touraine observes, however, that relatively little research has been carried out on the test's specificity; for instance, the possibility that leprosy gives a positive result has not yet been definitely excluded. With serum tests non-syphilitic positive reactions have been reported in infective mononucleosis and atypical pneumonia; and Touraine suggests that it is premature to conclude that with the *immobilisation test similar non-syphilitic* reactions do not occur. During treatment a steady decline in the degree of immobilisation suggests that therapy is succeeding. When, however, the patient has been insufficiently treated, or where treatment is started late in the disease, the test does not reflect the value of the therapy.

Touraine remarks that the technique of the test is complex and laborious; and the opportunities for technical error are much greater than with serum tests.

Treponemes are inoculated into the testis of a rabbit, and the testis must be removed at the right time. If it is removed too early, too few treponemes are obtained; and if too late, the test is vitiated by "auto immobilisins" produced by the animal. It has been suggested that the latter difficulty can be overcome by means of nitrogen mustard or X-radiation. Further difficulties can arise with the medium used in the test. The survival of the Nichols strain of treponemes used in the test depends on the medium being made up freshly from reliable components, and above all on the exclusion of oxygen during the incubation period. Success also depends on the density of the treponemes in the emulsion used (5 treponemes per dark-ground field), the serum concentration (10% in the final mixture), and the concentration of complement, on which the sensitivity of the test depends. The incubation period used is 18 hours, at a temperature of 37·5°C. The reading of the test is laborious, and one observer is not able to deal with more than 35 sera in a batch. If 50% or more treponemes are immobilised the test is reported as positive; if 20–50%, as doubtful; and if less than 20%, as negative. According to Nelson, if the control tube registers more than 30% immobilisation, the test should be reported as "inconclusive," or as "no valid test."

Touraine notes that in parallel periodic tests in a single case, the results of the immobilisation test may fluctuate whereas those of serum tests remain stable. Olansky et al.[10] showed that the test gave inconstant results with sera from malarial patients who had been inoculated with *Plasmodium vivax*.

Touraine declares that at present the immobilisation test should not be brought into general use; thus it will not become the focus of the arguments, errors, and hopes and disappointments that originally surrounded "sérologie classique." Clearly, before the test can be introduced into routine work, its specificity must be confirmed, and the technique simplified.

INTERNATIONAL HOSPITAL CONGRESS

No whit daunted by the thought of working when most others were enjoying a public holiday, participants in the Eighth International Hospital Congress came together from some forty countries in London last Monday for a week of discussions on the theme Preventive Medicine as a Major Function of the Hospital. This congress, like its predecessors, has been organised by the International Hospital Federation; and like its predecessors it had much of the air of a family reunion. The family is mixed; for the federation attracts as members not only doctors, but nurses, architects, administrators, and others concerned with designing and operating hospitals as well as those interested in central or local government. Perhaps the unusual opportunity for workers from different fields to exchange views breeds a happy expansiveness. The congress, under the chairmanship of Dr. René Sand, the federation's president, was opened by Mr. Iain Macleod, Minister of Health.

Prof. H. W. C. Vines contributed to the first plenary session a paper in which he rued "the academic blunder of the divorce of Preventive from Clinical Medicine, its forced marriage to Public Health, and the subsequent relegation of the unhappy pair to the isolation of a faintly depressed specialism." He drew attention to impediments in the way of preventive practice: these included the patient's reluctance to admit to illness until this was fully established (though the increasing cost of sickness might precipitate the requirement that all insured persons should be regularly examined), and the "curative" outlook of the medical profession. Hospitals, he suggested, should aim at improved coöperation with the domiciliary services, and should make a serious effort to prevent patients being admitted for trivial reasons. Hospitals tended to be obsessed with beds, regarding their outpatient departments as unwelcome appendages. Their preoccupation should be with outpatient departments where the patient could be treated while "still ambulant, still living his life with some semblance of normality among his own people, still perhaps able to were the same as those who took the diploma (except at University College Dublin), indicating that those who took the certificate proceeded to take the diploma.

Professor SCHLAPP said that the first point was the time before a candidate could enter for the certificate. Under present conditions this was a minor matter because most candidates had to do two years National Service after qualifying. It seemed that the rules were not fulfilling the purpose for which they were drawn up. The original idea was that the C.P.H. candidates should be more numerous than those for the D.P.H. He wondered whether the division into certificate and diploma courses was best educationally.

Sir ANDREW DAVIDSON said that it seemed clear that the intentions of the advocates of the C.P.H. were not being fulfilled. This certificate was no better than the old part I of the D.P.H. rules.

"I think the most important thing we have to ask ourselves is 'What are we training a person for?'" continued Sir Andrew. "If we are going to educate people in public health we must know what functions that person will have to perform, and adjust the education to those functions. It seems to me that a case could be made out for a revision of the rules but I did feel that the setting up of a committee just now might be a little premature—on the other hand it might act as a stimulus to the people who have to supply us with information."

Sir Andrew believed that, on balance, the council would be justified in setting up a committee to consider a revision of the rules and at the same time to advise the council on the recognition of Commonwealth diplomas under the 1950 Act.

Dr R. M. F. PICKEN agreed that the case for having a committee was a strong one. He thought that there was a case for abolishing the statutory requirement of the diploma in public health for posts. He had never been satisfied with any D.P.H. course prescribed by the General Medical Council: it was a mixture of incompatibles. It was clear that a number were taking the course who never needed it statutorily; that was one of the reasons why the certificate was invented. Wales always had far more C.P.H. students than D.P.H. students. In Wales they made it clear to an intending student that if he would not need the diploma statutorily, it would be better if he took something else—for example, the diploma in child health or the diploma in obstetrics.

Prof. A. P. THOMSON said that at Birmingham the policy was to avoid all diplomas, and they were unlikely to provide a course. They held that postgraduate training of this kind was a matter for a higher degree in medicine; they had no objection to theses in public health being submitted for the M.D. degree. Birmingham University considered that if the authorities insisted on a diploma, this was the affair of the Colleges.

The PRESIDENT remarked that the council was charged with the supervision of the diploma and it must carry out this duty. In view of the difficulties, a change in the law was unlikely.

The council agreed to set up a special committee on the lines indicated by Sir Andrew Davidson.

PROVISIONAL REGISTRATION

The council considered a report of a special committee on provisional and full registration. This contained an opinion from the legal assessor on provisional registration and a letter from the British Medical Association relating to house officers' salaries which also raised the question of appeal in the case of an individual who at the end of his period of service or during his service did not get a certificate of satisfactory service.

The PRESIDENT commented that this was a matter for licensing bodies. He thought that each individual licensing body, if it got an unsatisfactory certificate, would inquire into the reasons. It would be difficult to go behind an unsatisfactory certificate; it would be impossible to hold anything like a judicial inquiry. If the individual went to the West Indies to an approved post, for example, how could the licensing body find out what was satisfactory or not? They would be bound to accept the certificate as it was.

The council approved the revised form of certificate of satisfactory service, and authorised the president to sign the necessary order. The certificate as revised includes the name of a member of the consultant or specialist staff under whom the individual has worked.

The council approved reciprocal registration arrangements under section 1 (*b*) of the Medical Act, 1950, with the Province of Alberta.

Medical Disciplinary Committee

The committee began its sitting on May 20, with the President in the chair.

APPLICATIONS FOR RESTORATION

Charles Lockley Bikitsha applied for his name to be restored to the Register. Mr B. B. Gillis, his counsel, said that Mr Bikitsha's name was erased in 1952 following his conviction at Birmingham Assizes in July, 1951. The matter arose largely as a result of the sympathy which he felt for two women who sought him out and represented to him that their pregnancies were due to men of his own race.

The committee did not think fit to direct the Registrar to restore Mr Bikitsha's name to the Register.

Mr H. Brown, counsel representing *Ram Kissoon Nandlal*, who applied for restoration, said that Mr Nandlal had been removed from the Register in 1951 for having had intercourse with a woman patient.

The Chairman announced that the committee had not seen fit to restore the name of Ram Kissoon Nandlal to the Register.

Mohammed Farid was represented by Mr N. Leigh Taylor, solicitor, who explained that the applicant was in Mecca. His name was erased in 1943 following a conviction for manslaughter.

The committee did not restore Mohammed Farid's name.

The committee restored to the Register the name of *Brendan O'Carroll*, which was erased in 1948.

James Albert Scarers also applied successfully for the restoration of his name, erased in 1947.

Mr F. P. Winterbotham made a statement about the application for restoration by *Henry Charles Coutts Hackney*. Letters and certificates sent in support of the application were not written by the persons from whom they purported to come. A letter had been received from the applicant saying that owing to a septic foot he would be unable to attend.

After the committee had resolved not to restore to the Register the name of Henry Charles Coutts Hackney the Chairman said: "The question arises whether we should take any further action." The committee considered this matter in camera.

ADULTERY

Charles Kingsley Colwill, registered as of Richmond House, Aldenham Road, Bushey, Herts, M.R.C.S. (1924), M.B. Camb. (1926), was charged with infamous conduct in a professional respect for committing adultery with a married woman with which woman he had stood in professional relationship at all material times.

The Registrar was directed to erase from the Register the name of Charles Kingsley Colwill. This is subject to appeal to the Privy Council within twenty-eight days.

Nicholas Lupkovics, registered as of Compton Lodge, Higher Compton, Plymouth, M.D. Chile (1938), was summoned to appear on the charge of having been convicted of unlawfully making an untrue statement to procure a passport and of committing adultery with a married woman with whom he was alleged to have stood in professional relationship.

The practitioner had not been traced, and the committee, which decided to proceed with the inquiry, found the conviction proved and ordered the erasure from the Register of the name of Nicholas Lupkovics. He has twenty-eight days in which to enter an appeal to the Privy Council.

ADJOURNED JUDGMENT

In May, 1952, the committee postponed judgment for one year on *John Howard Crawford*, registered as of 16A Wimborne Road, Bournemouth, M.B. Leeds (1937), against whom they found proved charges relating to forms purporting to relate to certain persons which he sent to the local executive council work, and still in a condition perhaps where his complaint can be arrested." Professor Vines thought that the future outpatient department, or polyclinic, might be in the centre of the town, whereas its related inpatient department would be at the periphery. The hospital, forsaking "the silences of intellectual snobbery," should also be a centre of instruction on healthy living.

Prof. C. A. Romanzi (Genoa) declared that for effective preventive action the hospital must be integrated with the other health services. Dr. E. L. Crosby, president of the American Hospital Association, also insisted on this need, and on the need "for the education of the patient and his family while he is being treated in the hospital." Prof. G. Portmann (Bordeaux) was impressed by the possibilities of the outpatient department for prevention; but he sadly reflected, as have others, that "it is difficult to make the authorities see that a programme of preventive medicine is in fact a profitable investment."

THIRST

WE all know thirst as a blessing when we can pleasantly satisfy it, and a curse when we cannot. Anyone, however, who sets out to define the physiological mechanism and the clinical importance of thirst is likely to sympathise with the American who replied to a questionary on this subject with the words: "I could save you lots of time and useless research. It seems silly to spend money to learn information so simple it cannot be comprehended."[1] Is thirst produced by dryness of the mouth or throat, or is it due to a more general desiccation of cells, either throughout the body or in some special receptor analagous to, and possibly even identical with, Verney's osmoreceptors?[2] Cannon[3] suggested that dryness of the mouth was the cause, and demonstrated a decrease in salivary secretion; but this hardly amounts to proof, since thirst and diminished salivary secretion might be independent consequences of general tissue dehydration. Perhaps the strongest evidence against the buccal theory is that thirst is not relieved by the tantalising procedure of sham-drinking, in which water given freely by mouth is allowed to escape from an œsophageal fistula.[4] Thirst is readily produced by the injection of hypertonic solutions either of salt[5] or of sorbitol, sodium sulphate, and acetate.[6] Substances, such as urea, which enter cells have a much less striking and rapid effect, although their diuretic action may later lead to water-drinking. These experiments would suggest that a rise in the osmotic pressure of body-fluid is a potent thirst stimulus; a rise in serum-sodium is usually present, but thirst can be induced by other agents (sorbitol, for example) with which the osmotic pressure is increased but the serum-sodium reduced. The introduction of hypertonic solutions into the blood-stream is likely to have two effects on intracellular fluid—shrinkage in volume, and increase in osmotic pressure. When shrinkage in volume without increase in osmotic pressure of intracellular fluid was induced by potassium depletion, thirst was not observed.[7] Increase in osmotic pressure of body-fluid therefore seems to be the most firmly established thirst stimulus; but local factors may play some part in the mechanism, for thirsty men have been found to make good only part of their water deficit[8] and hypertonic saline diminishes salivary secretion.[9]

Despite large lacunæ in our understanding of thirst, its presence or absence can help us in assessing clinical problems; and Holmes and Montgomery[1] have reviewed thirst as a symptom. They, like Marriott,[10] regard thirst as pointing to predominant water depletion; and, again like Marriott, they comment on the absence of true thirst in salt depletion. Some patients do complain of thirst when depleted of sodium; but it must be difficult for untrained observers to distinguish between ordinary thirst and the unpleasant metallic taste observed by McCance[11] in salt depletion. It is also difficult to explain the thirst of patients with cardiac œdema, who quite often have a low serum-sodium[12]; Holmes and Montgomery suggest diminished salivary blood-flow and intracellular dehydration as alternative explanations. They make some interesting observations on the salivary flow in patients with diabetes insipidus and with functional polydipsia. In normal people and those with functional polydipsia pitressin either decreases the salivary flow or leaves it unaltered; in patients with diabetes insipidus pitressin causes a striking increase in salivary flow, which also results from forcing fluids beyond the level of urinary output. Hæmorrhage does not occasion thirst unless it is severe enough to lead to shock. Thirst, or at least dryness of the mouth, can also be produced by emotion.

The interesting review by Holmes and Montgomery should stimulate further clinical observations on thirst; and these workers point out that, apart from its practical value, inquiry about thirst always leads to a good story, for "everyone has had some particular experience with thirst, which he loves to recount."

RESEARCH ON POLIOMYELITIS

LABORATORY research on poliomyelitis is an expensive business, but recent progress in technique has made it possible to dispense with the costly monkey and to bring this work within the means of laboratories in the lower income groups. At a meeting of the epidemiological section of the Royal Society of Medicine on May 15, Dr. A. P. Goffe described some of these changes, and particularly those that followed the work of Enders et al.[13] on the growth of poliomyelitis viruses in tissue culture. He gave a demonstration of how he had been applying these techniques to the serological typing of poliomyelitis virus strains recovered in this country. Unfortunately, facilities in this country for laboratory investigations of poliomyelitis outbreaks are at present very limited, and Dr. F. O. MacCallum pleaded for the use of the available resources in studying one or two hand-picked problems, rather than testing all specimens submitted for examination. Which questions are to be investigated largely depends on how wide an expansion of laboratory facilities is contemplated. Perhaps the best argument for intensifying the attack on poliomyelitis by research in this country is the great progress made in the U.S.A. towards successful vaccines.[14] There are good reasons for hoping that practical vaccines will be available within the next few years, and until then there are many technical matters in the production and use of vaccines which would repay immediate investigation. The demand for vaccines is certain to be heavy and the cost of producing them high; and if they are to be manufactured in this country, it will be necessary to train people in the specialised techniques required for this exacting work. This work alone is clearly capable of absorbing a large proportion of the available laboratory facilities, and there are many other promising lines of

After considering testimonials the committee found him not guilty of infamous conduct in a professional respect

ALLEGED ASSAULT UNDER HYPNOSIS

Sidney Linton, registered as of Bentley House, Meanwood, Leeds 6, M R C S (1945), was charged with (1) having behaved improperly to, and committed adultery with, a single woman, and (2) that he stood in professional relationship with her at the material times

The committee determined that the facts alleged against Dr Linton under head one of the charge had not been proved to their satisfaction They accordingly found him not guilty of infamous conduct in a professional respect

CONVICTIONS FOR DRUNKENNESS

Florence Joseph O'Driscoll, registered as of 8, Moss Lane Orrell Park, Liverpool 9, M B N U I (1928), was charged with having been fined 10*s* at Liverpool on Feb 24, 1949, for disorderly behaviour whilst drunk, and of being fined 10*s* at the same court in 1953 for being found drunk

The Chairman announced that the committee had decided to postpone judgment until May, 1954

NAME NOT ERASED

In May, 1952, the committee postponed for one year judgment on *Daniel Topping Gemmell*, registered as of 81, Madison Avenue, Ward End, Birmingham, 8, L R C P E (1924) He had been fined £5 after being convicted at Bottisham Petty Sessions of an act of indecency

In view of the testimony to his conduct, the committee determined that the Registrar should not be directed to erase his name

DRUNKENNESS CHARGE

Patrick Aloysius Gallen, registered as of 355, Garscube Road, Glasgow, M B Glasg (1929), was charged with having been convicted of offences involving being in charge of a motor car whilst under the influence of drink

The committee postponed judgment for one year

CONVICTION FOR PROCURING DRUGS

Joseph Henry Bentley, registered as of Littlewick, Limpsfield, Surrey, L M S S A (1935), admitted conviction at the Magistrate's Court, Portsmouth, on Nov 7, 1952, of procuring morphine, contrary to the Dangerous Drugs Regulations, 1937, and of failing to keep a register of drugs

The committee postponed judgment for one year

DRUNKENNESS IN CHARGE OF CAR

At the sitting in May, 1952 the committee postponed judgment for one year in the case of *Thomas Patrick Smyth*, registered as of 32, Market Street, Atherton, Manchester, L A H Dubl (1939), who had been convicted in 1948 and 1951 of being in charge of a motor car when under the influence of drink or drugs

The Registrar was not directed to erase his name

Roger Keith Hayden, registered as of 4, Graham Road, Hendon Central, London, N W 4, M R C S (1943), was charged with having been convicted at Chelmsford on Nov 20, 1952, of driving a motor vehicle when under the influence of drink, of assaulting two police constables, and of committing wilful damage to cell windows He was further charged with having been convicted at Chelmsford on Dec 4, 1952 on five counts of obtaining cyclobarbitone, amphetamine, and codeine, by false pretences

Judgment was postponed for one year

Patrick Laurence Lyons, registered as of Highland Lodge, Kilkelly, co Mayo, L A H Dubl (1948), L.R F P S Glasg (1948), had been convicted in 1951 of driving or attempting to drive, or being in charge of, a motor vehicle when under the influence of drink or a drug

The committee postponed judgment for one year

POSTPONED JUDGMENTS

Thomas Leven, registered as of 2, Beech Avenue, Irvine, Ayrshire, L R C P E (1945), had been summoned to appear before the committee in November, on a charge of having been admonished at the Sheriff Court of Ayr in June, 1952, after having pleaded guilty to procuring in cumulo 567 grains of morphine sulphate by presenting, in the name of patients, prescriptions therefor to chemists

The committee postponed judgment for one year

The Registrar was directed not to erase from the Register the name of *Alan McKerlie*, registered as of 238, Upper Chorlton Road, Manchester, 16 M B Aberd (1937) Judgment in his case was postponed from May, 1952, when he had been found to have been convicted of being drunk and disorderly, of driving a motor car whilst under the influence of drink, and of assault

Patrick Kennedy, registered as of 53 East Dulwich Road, London, S E 22, L R C P I (1926), appeared before the committee In December, 1951, judgment against him was postponed for one year He was not present in November, 1952, and the committee postponed judgment until May, 1953 Dr Kennedy was now present He was told by the chairman that in view of the absence of satisfactory evidence as to his conduct, the committee had determined to postpone judgment for a further six months

---

LONDON TEACHING HOSPITALS

Boards of Governors

THE Minister of Health has made the following appointments, to fill vacancies caused by the retirement of a third of the members, to the boards of governors of the 26 London teaching hospitals Of 215 appointments, 164 are reappointments of retiring members There are 9 appointments outstanding The names of medical members are shown in bold type Those appointed will hold office until March 31, 1956

ST BARTHOLOMEW'S HOSPITAL

Reappointed Sir Herbert Cohen, O B E, **E R Cullinan**, F R C P, Prof J F Lockwood, PH D, Alexander McL Niven, J P, Sir Denis Truscott, **O S Tubbs**, F R C S, R R J Turner, O B E, J S Weatherley

New members **Geoffrey Keynes**, F R C S, F R C P, Lord Hardinge of Penshurst (until March 31, 1954)

LONDON HOSPITAL

Reappointed Sir Thomas Creed, K B E, M C, M A, Q C, Lieut Commander Horace Denton, O B E, R N retd, Mrs R C Littlejohn, **D. W C Northfield**, F R C S, Colonel V C Ponsonby, M C, Lieut Colonel W M Pryor, D S O, **Hermon Taylor**, F R C S, C S B Wentworth Stanley

New member Miss Irene Dowling

ROYAL FREE HOSPITAL

Reappointed Prof Winifred Cullis, C B E, D SC, W E Ford, **J D McLaggan**, C V O, F R C S, **Clifford Morson**, O B E, F R C S, Lady Bowen Thomas, Miss **B E Turner**, O B E, F R C O G

New members Miss M E Craven, Hon Mrs Gilmour, Prof **Esther Killick**, M R C P

UNIVERSITY COLLEGE HOSPITAL

Reappointed Mrs I M Bolton, Prof **S J Cowell**, F R C P, B Ifor Evans, **E A Gregg**, L.R C P I, J P, Mrs M Harvey, J P, Major General J C F Holland, C B, D F C, Sir Cosmo Parkinson, G C M G, K C B, O B E, A Shefford, O B E, one appointment outstanding

MIDDLESEX HOSPITAL

Reappointed Sir Eric Gore Browne, D S O, C G Izard, O B E, J C Maude, Q C, W B Morrison, S Whitbread

New members **H Wilkes Harvey**, F R C S E, J P, **F D Howitt**, C V O, F R C P, **R V Hudson**, F R C S, **Clifford Morson**, O B E, F R C S

CHARING CROSS HOSPITAL

Reappointed Mrs E O Lindgren, Howard Marshall, Sir John W Morris, C B E, M C, G A Pargiter, M.P, **David Trevor**, F R C S, Sir John Stewart Wallace, C B

New members Lieut Colonel C E G B Gond, M C Prof **W J Hamilton**, M D, Harry Hutchinson

ST GEORGE'S HOSPITAL

Reappointed J Bennie J P, Hon Mrs Reginald Coke, E O Durlacher, Mrs Helga Feiling Alderman W D Little Brigadier H L Roy Matthews **M F Nicholls**, C B E, F R C S Hon Sir Frank Soskice, Q C, M.P

New members Prof **T Crawford**, M D, **V H. Riddell**, F R C S

WESTMINSTER HOSPITAL

Reappointed Viscount Addison, Hon Mrs S Assheton, A N H Baines, **R Coyte**, O B E, F.R C S, **C J Gavey**, F R C P, Mrs M High, Henry Solomons, Sir Harry Vanderpant, two appointments outstanding

investigation to be attended to. One of them was indicated by Dr. J. Stevenson Logan at the Royal Society of Medicine when he described the high prevalence of paralytic attacks of poliomyelitis in school-teachers. This observation suggests an opportunity for the laboratory to help in tracing the precise path of infection in a particular school. For one thing, preventive measures could be planned more rationally if we knew whether the virus was spread by direct contact or by droplet infection.

The meeting was very interested in the possible uses [illegible] Dr. Goffe used some sobering [illegible] his view that gamma-globulin could be used only in small numbers of cases. Indeed, Hammon et al.,[15] who described the promising gamma-globulin trials in the U.S.A., do not believe that its widespread application is practicable.

ACNE VULGARIS

ACNE vulgaris is almost a normal accompaniment of puberty; but if it is severe, or if it persists beyond the 'teens, then some reason has to be found. According to Wittkower[16] people with acne are arrested in their emotional and psychosexual development at the stage of puberty, with no corresponding delay in physical development: the menarche, for example, does not vary from the normal. This suggests that acne is caused by emotional disturbances connected with puberty as well as the physiological processes of maturation.

Lorenz et al.,[17] postulating that in acne emotional influences must operate by quantitative or qualitative alterations in sebum secretion, have devised a method of collecting sebum specimens for study. They obtain their material from that sebum-rich area—the angle of the nose. The skin is first cleaned with ether so that the quantity of sebum subsequently collected represents the amount reappearing on the skin-surface in a given time. The apparatus consists of a hollow glass rod, the ground end of which is applied to the skin under a pressure of 400 g. for 5 seconds by means of a piston-shaft with a metal sleeve at one end for holding the glass rod and with a coiled spring in its hollow handle at the other end. They find that the "control" level of facial sebum output is much the same in acne and in normal patients, and that facial sebum secretion is stable during periods of tranquility although there are day-to-day fluctuations.

In patients with acne, however, sebaceous glandular function is labile, with abrupt fluctuations in facial sebum output under stressful circumstances. These patients have a labile affect, highly characteristic and stereotyped. They respond periodically with feelings of intense anger for brief periods, promptly followed by more prolonged feelings of remorse (guilt and depression), usually set up by conflict with some figure of authority, especially a parent. The daily lives of these patients are punctuated by distinct swings in affect. There is a close association between this emotional lability and fluctuations in sebum output, and the rapid phasic mood-swings are closely related to the number of facial pustules. Stressful interviews with such patients were associated with increased sebum secretion when anger was elicited, and with decreased sebum secretion when the patient responded with remorse. No significant changes in sebum secretion arose from non-stressful interviews with these patients, nor during stressful interviews in a control group of patients without acne. Lorenz and his colleagues suggest that abrupt phasic alteration in the rate of sebum secretion is an important factor in comedone formation; stasis, inspissation, and other physiochemical changes, they say, occur in the hyposecretory phase and lead to impaction of sebum in the next hypersecretory phase, so that the acne is exacerbated after 24–48 hours. Skin-temperature may influence the viscosity of sebum and hence stasis and plug formation, and Lorenz et al. believe that the pronounced vasomotor changes associated with variations of mood may cause wide fluctuations of temperature in the skin. It is perhaps significant that acne vulgaris mainly affects the face, upper chest, and back—the "blush" areas of the body.

The sebaceous glands are not under direct nervous control, but they respond to endocrine stimuli. The nervous control of the sweat-glands can, however, to some extent influence the spread of sebum on the surface of the skin, hyperhidrosis leading to more emulsification and spread of the skin fat. Aron-Brunetière[18] suggests that the neuro-endocrine pathogenesis of acne is somewhat as follows: a disequilibrium in the hypothalamo-pituitary mechanisms disturbs the production of pituitary gonadostimulins with the result that the balance of the steroid hormones is upset towards an excess of androgens (and, in women, progesterone) over œstrogens. Haskin et al.[19] have shown that in the rat the administration of progesterone produces an increase in sebaceous-gland size comparable to that induced by testosterone; and these workers, too, suggest that adolescent acne in the female is related more to progesterone/œstrogen imbalance than to androgen/œstrogen levels.

NOVO ZINC INSULIN

RECENT clinical trials[20] [21] in this country have done much to confirm the claims of the Danish Novo Terapeutisk Laboratories that their new insulin represents an advance on all previous insulins. Hallas-Mollerd an his colleagues[22] made the relatively simple discovery that the addition of small quantities of zinc to dissolved crystalline insulin in acetate buffer precipitated the insulin over a wide range of pH, including that of the body-fluids. This fact had previously been obscured because phosphate is sometimes used as a buffer for insulin, and added zinc is precipitated as zinc phosphate rather than combined with the insulin. There have been suggestions of an interesting relation between zinc and insulin for a long time; for example, it was known that the pancreas contained a higher proportion of zinc than any other organ, and that the addition of large amounts of zinc to soluble insulin[23] or small amounts to protamine insulin[24] prolonged their respective actions. The Danish zinc insulin precipitate also has a long-continued action. Zinc insulin crystals form when zinc chloride is added to dissolved crystalline insulin, buffered with acetate to a pH of between 4·5 and 5·8, whereas outside this pH range the precipitate is amorphous. The fact that the zinc insulin crystals, once formed, are stable over a wide range of pH is of great practical importance. The duration of the effect of these insulins depends largely on the size of the particles in the precipitate. Thus, zinc insulin crystals 100 μ long exert a hypoglycæmic action for more than thirty hours in man, whereas the finer amorphous zinc insulin particles act for some twelve to fourteen hours. The Danes have also made up an intermediate variety containing both crystalline and amorphous forms of zinc insulin, and this lasts about twenty-four hours. Each variety contains nothing but thrice

ST MARY'S HOSPITAL

Reappointed **Richard Doll,** MD, I M Gluckstein, A H Lee, Lord McGowan, KBE, Prof **W D Newcomb,** FRCP, Lady Plummer, Miss **Esther Rickards,** FRCS, H L Smedley

New members **D F Hutchinson,** OBE, MRCS, **G L M McElligott,** MRCS

GUY'S HOSPITAL

Reappointed S B Askew, R H Burslem, JP, E V Evans, OBE, DSC, Prof **T B Johnston,** CBE, MD, K I Julian, CBE, Richard Newton, Prof **W R Spurrell,** FRCS, **F S Warner,** MRCS, FDSRCS

New members Brigadier Archer Clive, A. E Orchard Lisle

KING'S COLLEGE HOSPITAL

Reappointed **Ralph Cocker,** MB, FDSRCS, **Terence East,** FRCP, Squadron Leader G Edgar, G Hart, H Lock Kendell **Sidney Thomson,** FRCP, Hon Mrs Charles Tufton, O.BE

New member Mrs M E Davis, JP, one appointment outstanding

ST THOMAS'S HOSPITAL

Reappointed R J Sainsbury, MA, ACA, Mrs D A Thomas, Sir Herbert Thompson, CIE, MA, **N E Waterfield,** OBE, FRCS, S W Whiffen, C R N Winn, C.B, OBE, MA, LLM, **J M Wyatt,** FRCOG

New members **R H. Boggon,** FRCS, Mrs Margaret Mitchiner, **J S Richardson,** MVO, FRCP

HAMMERSMITH, WEST LONDON AND ST MARK'S HOSPITALS

Reappointed Prof **Ian Aird,** FRCS, E G Anthony, J.P, J Bennie, JP, Mrs M Griffith, Dame Katherine Jones, DBE, RRC, SRN, Mrs R K Judges, **H R Thompson,** FRCS

New member **R H Franklin,** FRCS one appointment outstanding

HOSPITAL FOR SICK CHILDREN

Reappointed Mrs B A Beaumont, JP Hon Margaret Bigge, **W C V Brothwood,** MD, **I A B Cathie,** MD Mrs E M Fell, **G H Macnab,** FRCS, Lady Thomas

New member Edith Batho

NATIONAL HOSPITAL FOR NERVOUS DISEASES

Reappointed **Macdonald Critchley,** FRCP, Hon Mrs Lyttelton, Countess of Rothes, Sir Norman Strathie, W H Taylor

New members Sir **Charles Symonds,** K.BE, CB, FRC.P, **Harvey Jackson,** FRCS, Sir John Woods

MOORFIELDS, WESTMINSTER AND CENTRAL EYE HOSPITAL

Reappointed N E Behrens, **F W Law,** FRC.S, Bryn Roberts, A P D Smyth, Miss V Spenser Wilkinson, Sir John Stainton, KBE, QC

New members **P McG Moffatt,** FRCS, Lady Dunbar Nasmith, CBE

BETHLEM ROYAL AND MAUDSLEY HOSPITALS

Reappointed W J Bourne, Prof **A J Lewis,** FRCP, Prof **Alfred Meyer,** MD, **T A Munro,** MD, E V M Stockdale, Sir Frederick Wells

New member T S Stigger, one appointment outstanding

ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN

Reappointed **F R Bettley,** FRCP, **G M Frizelle,** MD, Sir **Archibald Gray,** CBE, FRCP, H. Gutteridge, MIMECHE, H Whitbread, MA

HOSPITAL FOR DISEASES OF THE CHEST

Reappointed Mrs M G Burton, J H Cooke, **A Hope Gosse,** FRCP, Sir **Bennett Hance,** KCIE, OBE, MD, A. J Newman, **F H. Young,** OBE, FRCP

New members Hon Michael Astor, J W Randall Naton, JP, one appointment outstanding

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL

Reappointed A E Reneson Coucher, FRICS, **A T Fripp,** FRCS, Sir Howard Kerr, KCVO, CMG, OBE, Miss Grace Rattenbury, M.A., **H J Seddon,** CMG, FRCS, Lady Sherwood

New member Angus Mackinnon, DSO, MC (until March 31, 1955)

NATIONAL HEART HOSPITAL

Reappointed **R C Brock,** FRCS, **J Maurice Campbell,** OBE, FRCP, L H Watts, Mrs E V Whiter, one appointment outstanding

ROYAL NATIONAL THROAT, NOSE AND EAR HOSPITAL

Reappointed Mrs D E Clark, A G Farr, G F Higginson, Prof **F. C Ormerod,** FRCS, J R Roselli, Mrs A Rye

New member A C Crouch

ROYAL CANCER HOSPITAL

Reappointed **A Lawrence Abel,** FRCS, D E W Gibb, D A J Jackman, MBE, JP **E E Pochin,** FRCP, W G Wilsher, F Griffiths Woollard, DL, BSC, JP

New member Sir Edgar Sylvester, KBE, FCA

QUEEN CHARLOTTE'S AND CHELSEA HOSPITALS

Reappointed **Frank Cook,** FRCS, Admiral J H Godfrey, C.B, Hon Mrs E Hodgkin, Frank Ramseyer, **J M Wyatt,** FRCOG

New members **Briant Evans,** FRCS, **S G Clayton,** F.RCOG (until March 31, 1955), R D Forshaw

EASTMAN DENTAL HOSPITAL

Reappointed Sir **Allen Daley,** FRCP J G Girdwood, OB.E, Prof **W E Herbert,** MRCS, Miss K G **Lloyd Williams,** MD

New member I R H Kramer, L.D.S

ST PETER'S AND ST PAUL'S HOSPITALS

Reappointed H Lythgoe, Colonel A R Martin, H M Tobin, **R Ogier Ward,** OBE, FRC.S

New members **A W Badenoch,** FRCS, **J D Fergusson,** FRCS one appointment outstanding

Parliament

QUESTION TIME

Medical Appointments in the Civil Service

Dr A D D Broughton asked the Financial Secretary to the Treasury what information he had received from the British Medical Association with regard to its refusal to publish advertisements of vacant medical appointments in the Civil Service, what was the subject at issue that had given rise to this decision, and what action he was taking to remedy the situation —Mr J A Boyd Carpenter replied The British Medical Association indicated some time ago that, if advertisements of these posts were offered for insertion in the *British Medical Journal,* they would not be accepted, and I received on May 7 a letter from the association saying that they still adhere to that decision Vacancies are not now being advertised and therefore no question of refusal to insert advertisements at present arises The reason, I understand, for the British Medical Association attitude is that they do not regard as satisfactory the present salaries, which are those recommended by an independent committee under Sir Harold Howitt's chairmanship in 1951 I have discussed the matter several times with a joint committee of the British Medical Association, the Medical Staff Association of the Ministry of Health, and the Institution of Professional Civil Servants, and I offered to reconvene the Howitt Committee to review the present salaries This offer was rejected I have made other suggestions for settling this matter, but so far without result

Consultants in the N H S

In answer to a question Mr Iain Macleod, the Minister of Health, stated that the number of whole time consultants in England and Wales at Dec 31, 1952, was 1800 The corresponding numbers for 1950 and 1951 were 1529 and 1650 The number of part time consultants doing maximum sessions was not available The percentage of whole time specialists among all consultants had climbed steadily in each of the last three years Although there had been an increase in the number of part timers the percentage was less than the increase of the whole timers crystallised insulin combined with zinc (2 mg. per 1000 units) and suspended in saline and acetate buffer to bring the pH to 7·2. Each of the three varieties can be mixed with either of the others, but not with the commercial insulins which contain phosphate. Moreover, mixtures of the different varieties are stable and can therefore be premixed in vials for each patient's individual needs.[21]

The Danes claim that 90% of all diabetics needing insulin can be successfully treated with a single daily injection of an appropriate zinc insulin preparation; the insulin requirements of the other 10% show such wide and spontaneous fluctuations that no one-injection régime would be satisfactory. A similar claim has been made for NPH insulin, which has a duration of action that suits most diabetics. There is, however, the important factor of the individual response to a given diet and insulin dose, and this response is surprisingly variable. If the action of NPH insulin proves to be too long delayed, the time can easily be shortened by mixing in a proportion of soluble insulin. But if the action of NPH is too short, nothing can be done to lengthen it; and here lies one of the main advantages of the new series of zinc insulins which can be graded to cover a wide range of action. Another advantage is their purity and freedom from added protein, which makes local skin sensitisation unlikely. In fact no cases of skin sensitivity to these insulins have so far been reported, in spite of their use in patients known to be sensitive to other insulins.[21] The simplicity of the ingredients of the Novo zinc insulins means that uniformity of action from batch to batch is more likely, and preliminary studies by Oakley [25] suggest that this is so. It would at present only complicate matters to add the three grades of Novo zinc insulin to the three types of insulin already in this country, but few would claim that our present insulins are ideal. It seems reasonable, therefore, to give a wider trial to Novo zinc insulins, under carefully controlled conditions, to provide adequate data on which to decide whether they can replace globin and protamine zinc insulin altogether.

LA MÉDIASTINOGRAPHIE GAZEUSE

THE display of a mass by X rays is chiefly determined by the contrast between it and its immediate surroundings. Apart from fat, and structures containing much calcium, the density of all body tissues is approximately the same; and, no matter how large a lump may be, unless at least a part of it is surrounded by shadows of different density it will be very difficult or impossible to define.

In the study of mediastinal abnormalities this handicap is particularly severe, and a group of French workers [26] have been trying to improve the accuracy of diagnosis in this field by injecting air into the mediastinum, to supply the necessary contrast. The air is introduced into the deep tissues of the neck through a needle transfixing the trachea. This method has been used in over 50 cases without serious mishap. There have been no air-emboli, and the authors claim that caval compression does not occur since the air can easily escape up into the neck and down into the abdomen. Up to 700 c.cm. is introduced; and then a *full radiographic* examination is made, including if necessary barium swallow, tomography, and cardioangiography.

This method certainly yields startling pictures, but it seems unlikely to help in answering the two questions most important to the surgeon—namely, is the lesion malignant, and is it operable? Thus the method is unlikely to supplant thoracotomy.

MAXIMUM BREATHING CAPACITY

MAXIMUM breathing capacity is usually measured by causing the patient to breathe for a quarter of a minute as deeply and quickly as possible to and from a recording spirometer with a light aluminium bell and without a CO_2 absorber.[1] The result, obtained from a kymograph tracing of the movements of the bell, is expressed in litres per minute or in litres per minute per square metre of body-surface. Various modifications of this technique have been described.[2]

The difference between the maximum breathing capacity (M.B.C.) and pulmonary ventilation—the breathing reserve—is normally more than 90% of the M.B.C. when the patient is at rest. When the reserve falls to 60–70% of the M.B.C., either by restriction of the M.B.C. or increase in ventilation, dyspnœa is felt. In health this only happens during exercise, but in the patient with pulmonary disease it may occur at rest [3]; and in this event not only is the M.B.C. low but ventilation is often high. The M.B.C. is the dynamic equivalent of the vital capacity, which may be regarded as a static measurement of the bellows action of the thorax and lungs. The relationship between these two measurements has lately been examined,[4, 5] and a close correlation has been established between the volume of the first part of a maximum expiration, which is delivered most rapidly, and the M.B.C. This fact allows a fairly accurate prediction of the M.B.C. to be made from tracings of the vital capacity; moreover estimates made in this way are less liable to be influenced by subjective error or practice effects, particularly when questions of compensation are at stake.

In normal people the maximum ventilation during exhausting exercise is not as great as the M.B.C.,[6] but, by contrast, in some severely incapacitated patients the M.B.C. is actually less than the maximum ventilation on exercise. It has recently been shown that the work done in ventilating the lungs is less when the ventilation is brought about by exercise than by a voluntary hyperventilation, owing to a decrease in the viscous resistance of the lungs during exercise.[7]

Within wide limits pulmonary ventilation varies directly with increase in oxygen consumption or external work. The relation between these two, however, is not identical from subject to subject; for a given increase of oxygen consumption one patient may ventilate much more than another, and his breathing reserve be less in terms of the work he can do. Thus, even if in two such cases the breathing reserve at rest is identical the amount of effort which they can put out may differ.[8]

Only when maximum breathing capacity is much impaired is the patient's activity noticeably limited. Thus, whereas an athletic young man may have a M.B.C. of 150 litres per minute, many who consider themselves normal have M.B.C.s of about half this or even less: patients with M.B.C.s of 70 litres or more per minute are usually free from troublesome dyspnœa on ordinary effort. Although fundamentally the M.B.C measures only the bellows function of the lungs it is usually diminished by any functional disturbance of the respiratory system even when this is not primarily mechanical. Thus, like the vital capacity, the M.B.C. may be used as a non-specific indicator of progress in the functional evolution of disease.

In England Now

A Running Commentary by Peripatetic Correspondents

AT the annual meeting of the National Association of Malingerers, held this week in London, Dame Lydia Languish was elected to the chair in succession to Baron Münchausen, who has been appointed adviser extraordinary to the Persian Plenipotentiary

The council noted with pleasure the loyal greetings sent by the Malades Imaginaires de France, but they regretfully decided that they could not offer hospitality for the Coronation to their Gallic colleagues Their own members were going to have difficulty in getting a good view of the procession despite the general lending of televiewers to hospitals "Many hospital R M O s," commented Dame Lydia, "are unsympathetic to our members, and outpatient E C T has proved a deterrent to many who could normally have expected a comfortable bed from which to view the ceremony "

A ballot of the members was taken for the allocation of the Hyde Park Corner zone to three members A general discussion followed as to the techniques to be employed by those successful in the ballot In an acute abdomen, it was suggested, the onset of pain should not be too early, as this could mean postoperative transfer to a country branch before June 2 Too late, it could involve the patient in postoperative pain, gastric suction, and other procedures which, although satisfying in themselves, could mask the interest the procession should demand Status epilepticus was likewise regarded with suspicion, as psychiatrists are often on hand in the hospital, and it again carries a risk of transfer It was finally decided that one member should develop renal colic and another status asthmaticus on June 1

Miss Lily Hepar, the association's consultant on pernicious anæmia, advised the pallid third ballot-holder to faint in the Underground, while protesting violently that she was quite well Miss Hepar offered to lend her own subicteral eye-drops to her colleague for the occasion She doubted whether the hæmaglobin could be checked the same evening Other members suggested an acute slipped disc, but it was pointed out that this could involve a mirror view

Dame Lydia emphasised that other members were on their honour not to trespass on the ballot-holders' field She thought, however, that any member who held the association's diploma could probably achieve the front row by performing near the Boy Scouts

The smallpox in the West Riding is virulent where the unvaccinated are concerned and precautions against its spread are strict A "contact" who had had a small boil on his leg the previous week was sent home from the colliery where he worked because he was not feeling very well When he presented a certificate of incapacity for work on the grounds of being a "smallpox contact" the local National Insurance office with admirable presence of mind and coolness burnt the contaminated piece of paper in the interests of public safety Not until he could produce a new and healthier certificate for a boil could the unfortunate collier get his money

* * *

You and I, gentle reader and gentle writer respectively, manage to get along nicely without the word "Methodology" We would willingly take the pledge never to let it pass our lips, or ginger up our graffiti The first time I came across it, it conjured up a picture of a plump woman in a large hat playing a harmonium and singing a sacred song Tears were running down her face (But that was one of my schizophrenic fancies Association of ideas—portmanteau word Methodist-Doxology Query—Primitive Methodology or Wesleyan ditto ? In either case, why the tears ? I dunno) Unfortunately it doesn't mean that at all Oddly enough although American scientific writers have made a corner in it, and will expend it five times in the second paragraph of an article, it is in fact an English word, and is registered in the 1929 edition of *Chambers's Dictionary* There it is defined as the "Science of method in scientific procedure" A splendid idea I wonder why we don't take to it We sometimes ask ourselves—"How can such-and-such best be accomplished ?" and proceed to discuss ways and means But can that be the same thing ? One can't be *quite certain*.

Quite a lot of splendid words crop up in Scientific American for which an American-English dictionary would be essential, did such a book exist As it is, one has to guess the meaning, check it roughly by the context, and hope for the best If it is an adjective, of course, one mentally removes it from the sentence to see if anyone is any the poorer Such an adjective is "Organizationalized," which is *not* in *Chambers's* and which one never meets here even in bureaucratic circles, but which may easily occur three times in five lines (usually at the beginning) of an American article Obviously it has no synonym, or who would use it and go on using it ? One has a vague idea as to what it may mean, but no exactitude

More and more I am forced to recognise that English and American are two different languages Their deceptive similarity sometimes plunges the English reader into disastrous misinterpretation, but more often leaves him with a wretched margin of uncertainty about the exact translation We ought to be warned by our French experiences of these homonymous pitfalls Think of the difference between "assister à une opération" and "assist at an operation" In the good old days it might have been as much as twenty guineas

* * *

The bad habit of adding a second serpent to the staff of Asclepios is often deprecated on the grounds that it suggests that our proper deity is Hermes, god of travellers, merchants, and liars But are we not being over-hasty in disowning Hermes ? Listen a moment to Guerber on the *Myths of Greece and Rome* "Hermes escorted the souls of the departed to Hades, and in that character was called Psychopompus, under the name of Oneicopompus he was regarded as the lord of dreams and visions" Surely the psycho-analysts are the modern guides through purgatory to the Elysian fields of the integrated personality, and they, at least, are entitled to the two-snaked caduceus and the patronage of Psychopompus himself

* * *

I've just met my most uncommunicative patient The battle went thus

"Good morning," I said, "tell me what you've noticed wrong with yourself"

"Nothing," she said

"Are you perfectly fit ?"

"Yes"

"Then why are you in the hospital ?"

"Because I got a telegram telling me to come"

"Then why," I continued, "did you come to the outpatients in the first place ?"

"Doctor sent me"

This line of approach was not proving exactly helpful I tried another "Have you any pain ?" I asked

"Oh yes," she said

"How long have you had it ?"

"I don't know"

"I'm sure you must know—is it a day, a week, or what ?"

"Oh no," she said

"Oh no what ?"

"I mean 'yes'"

"Well how long then ?"

"A long time"

"How long is that ?" I asked

"Quite a while," she said

As she made no further offer as to time, I suggested "Is it a week, a year, or ten years ?"

With the conviction of an expert witness she said "Yes"

As a matter of interest she proved to have hypertension, angina pectoris, and deep-vein thrombosis of the calf

News from Hospital—Counsel cross examining night sister at the Medical Disciplinary Committee Do you make any records of visits by doctors ?

Sister No I'm afraid we don't consider them important *enough* pe, should be warned to take carbohydrate in adequate mounts and not to miss a meal or a mid-morning or id-afternoon snack when on the road. He was more ubious about the suitability of a diabetic for driving a ublic vehicle or for piloting an aeroplane. He strongly issented from the view of another speaker that a lawyer as entitled to pick holes in the police surgeon's evidence, o get his client off.

Dr. G. M. KERR said that attention should be paid to oss of judgment and increased reaction-time, both of hich preceded motor incoördination and might result n serious errors in driving.

Dr. LINDSEY BATTEN said that the legal casuistry nvolved in quibbles about the colour of the accused nan's eyes was calculated to keep any but the most stout-hearted doctor from venturing into court.

Dr. G. J. V. CROSBY said that it was often an invidious task for a doctor to dissuade elderly private patients from continuing to drive. One of his patients who drove a high-powered car at a reckless speed was extremely annoyed at the advice that he should give up driving after he had had three blackouts in a year and had been found to have petit mal.

MANCHESTER MEDICAL SOCIETY

Pituitary Adenomata

AT a meeting of the section of medicine of the Manchester Medical Society, on Dec. 3, Sir GEOFFREY JEFFERSON, F.R.S., spoke on the Varying Behaviour of Pituitary Adenomata. He said that some pituitary adenomata behaved in a toxic fashion, while others were inert. The "toxic adenomata" produced gigantism, acromegaly, and basophilism—although he shared the general doubt about basophilism being primarily a pituitary disorder. The chromophobe adenomata produced varying degrees of hypopituitarism; some eventually caused a drift towards Simmonds's disease.

Sir Geoffrey based his remarks on 316 adenomata. He had operated on 250; 11 showed locally invasive properties. Sugar-tolerance curves had not shown any significant trends, though the toxic adenomata were more liable to give rise to glycosuria. Neither the metabolic-rate nor the eosinophil-count showed any uniform change. On the whole the urinary output of gonadotropins was more often reduced than that of the 17-ketosteroids. The dangers of operation were related more to hypothalamic disturbances than to acute stress syndromes. The enlarged sella turcica seen in radiographs gave an inadequate idea of the actual size of the adenomata, of which sizeable supra-sella extensions were extremely common—a fact easily demonstrated by pneumo-encephalography.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY

Outpatient Problems

AT a meeting of the Devon and Exeter Medico-Chirurgical Society on Dec. 18, Dr. W. A. LISTER spoke of common outpatient problems.

The first was that of the child who persistently coughed at night. This cough started about the age of 2, often after pertussis and pneumonia. The patient was intelligent, quick, alert, impatient, growing fast, and rather pale. Associated complaints were abdominal pains and persistent nasal catarrh. Inquiry revealed that the mother had taken the child to many doctors, hospitals, and clinics; but still the cough continued. In the causation these were the main factors: (1) an infective focus in the throat, nasopharynx, or sinuses; (2) a psychosomatic factor (the patient was often the only child of anxious parents); and (3) a dietetic factor, usually an intolerance of fat. If these patients are recognised as early asthmatics other things fell into place. Focal infection must be dealt with; this would improve but not cure the patient's condition. The psychological side should receive attention, perhaps at a child-guidance clinic. Dietetic measures consisted in reducing intake of fat and increasing intake of carbohydrate. Skin tests were disappointing; but common allergens, such as feathers, hair, and pollen, should be avoided as far as possible: the removal of the domestic cat sometimes produced striking improvement. The breathing exercises advocated by the Asthma Research Council were of great help.

Dr. Lister's second problem was that of the mild melancholic. Such patients often complained of vertical headache or pressure, or of boring pain in the temporal region. The condition was apt to follow the receipt of bad news and to occur in elderly men with an enlarged prostate. A carefully recorded history would often elicit evidence of previous attacks. Skin rashes, night waking in the small hours, and withdrawal of interest from customary occupations were characteristic. Organic disease must, of course, be carefully excluded before melancholia was diagnosed. Treatment consisted in attacking the night waking with phenobarbitone and countering the consequent morning hangover with '*Benzedrine*.' (*The* depression was worse in the morning.) If these measures failed electroconvulsive therapy often succeeded.

Dr. Lister's third problem was that of back strain producing persistent and otherwise inexplicable pain. Such pain might be due to minor degrees of root irritation on the concave side of a scoliosis. Poker-back followed prolonged and unnecessary decubitus. Both types responded well to physiotherapy.

Dr. CHARLES WROTH deplored the lack of liaison by which the same patient might be repeatedly and unnecessarily examined radiographically in various clinics and hospitals, or even in the same hospital.

Reviews of Books

Heredity in Uterine Cancer

DOUGLAS P. MURPHY, M.D., F.A.C.S., assistant professor of obstetrics and gynæcology and research associate, Gynecean Hospital, Institute of Gynecologic Research, University of Pennsylvania. Cambridge, Mass.: Harvard University Press. London: Oxford University Press. 1952. Pp. 128. 16s.

Dr. Murphy is right in thinking it important to determine whether heredity plays a part in the ætiology of uterine cancer, not only from the point of view of the woman whose mother has died of the disease, and who is therefore apprehensive for herself, but also from the point of view of those who have to diagnose and treat it. This book describes a well-planned, controlled investigation into the cancer incidence of near female relatives (mothers, sisters, female first-cousins, and their mothers) of 201 women suffering from cancer of the uterus, no attempt being made to distinguish cancer of the cervix from that of the body. The author concludes "that there is evidence for a rôle of inheritance in uterine cancer"; but that the quantitative effect is small and has not been measured with high precision. He is also of the opinion that the factors which predispose to uterine cancer do not predispose in any significant degree to cancer in other sites, but that hereditary factors do play a part in the ætiology of cancer elsewhere in the body. No significant tendency to concentration in particular families could be detected. The study is similar in plan to that of Brobeck,[1] made in 1949, and in general the results are similar.

The data took nearly three years to collect and at least four years to analyse. Four field workers were employed, and 890 patients diagnosed as having cancer of the cervix were visited, in order to secure records of 201 cancer family groups. The

ROYAL SOCIETY OF MEDICINE

Fitness to Drive a Vehicle

THE section of general practice met on Dec 17, under the chairmanship of Dr E P SCOTT, president of the section, to discuss Fitness to Drive a Vehicle

Dr R D SUMMERS, a divisional police surgeon in the Metropolitan area, said that in Great Britain during 1951 there had been 1309 road accidents thought to be caused by drivers who were under the influence of alcohol Many such drivers escaped conviction because the reluctance of the courts to find the accused guilty made the police unwilling to press the charge He himself did not certify some 35% of drivers referred to him as being under the influence of alcohol The charge, under section 15 of the Road Traffic Act of 1930, was concerned with being under the influence of alcohol or drugs to such an extent as to be unable to take proper charge of a motor vehicle The phrase about being in charge was sometimes rather unfairly interpreted, for a motorist who felt himself the worse for drink and who stopped his car to get into the back seat for a sleep was still technically in charge of the vehicle and could therefore be convicted of an offence The police surgeon, or the private doctor whom the accused person could call to examine him, must make a complete and thorough examination For this the consent of the accused must be obtained, and it was wise to have a witness to this consent and to the subsequent examination It was not unknown for the accused to assault the police surgeon or to attempt to escape from custody The pulse-rate should be taken at both the beginning and the end of the examination, during alcoholic intoxication the pulse was full and bounding, with a rate between 100 and 140 Full notes should be taken at the time, and every system thoroughly examined, particular attention being paid to any impairment of muscular coordination, the state of the pupils, and general behaviour It should be remembered that defending counsel could completely destroy the value of a careful clinical examination by disclosing, during cross examination, some gap in the doctor's observations For instance, the doctor might have made careful notes of the state of the pupils, but a jury would be led to think his evidence worthless if he had to admit in court that he did not know the colour of the eyes The history of any previous illnesses should be noted, and the events leading up to the accident, especially the taking of food and drink, should be investigated Evidence of the present mental state, speech, gait, and writing should be recorded Dr Summers usually asked the accused to copy a section of the Highway Code relevant to his charge, it was important to produce any specimen of handwriting in court The doctor must confine himself to the condition of the accused at the time when he examined him, and refuse to be drawn into speculations about his state at the time of arrest, which might be an hour or more previously The accused might ask for his own doctor or any other doctor to be called to examine him, as a defence against the findings of the police surgeon Such additional examinations did not come under the provisions of the National Health Service, and any doctor was entitled to refuse, or to charge a fee for his attendance If the police surgeon, having examined the accused, did not consider him to be under the influence of drink, the police very seldom prosecuted When the driver was found to be under the influence, the charge was heard next day in a magistrate's court The accused might be granted a remand to apply for legal aid, or he might elect to go for trial by judge and jury at the County Court, or to be tried by the magistrate

Dr F E CAMPS said that he thought the main duty of the doctor was to exclude the presence of organic disease, for if no disease was found to account abnormal behaviour, and it could be proved that t person had taken alcohol, then it was a reasonable infer- ence that his inability to control a vehicle was due to alcohol Several drugs simulated the effect of alco on judgment and coordination, but it was equally offence to be under the influence of drugs unless it co be shown that they had been taken in normal dosage the ordinary course of medical treatment The barb turates, nowadays widely prescribed, were commo blamed for inability to control a vehicle, and lately anti-histamines had joined them, whilst diabeti taking insulin often pleaded hypoglycæmia in defence In one case alkalosis had been brought forward as defence by a man suffering from a gastric ulcer who had take several spoonfuls of sodium bicarbonate—and also large quantity of whisky

Any organic nervous disease causing incoordinatio such as states of chronic cerebral contusion ("punch drunk"), acute concussion, epilepsy, vertigo from an cause, and Ménière's disease, might be the basis of defence

Dr Camps thought that the behaviour of the accu at the time of examination was the most important poin for the police surgeon to note Most private doctors were for obvious reasons, loth to attend even when the were asked to see their own patients They also we afraid of being involved in a legal case, mainly becau of having to face cross-examination by counsel—whic should be no cause for worry Others, however, dislike hanging around courts waiting for the case to be heard, th could be avoided by approaching the clerk if necessary

Mr L C. NICKOLLS, director of the New Scotland Yar laboratory, spoke of the value of the tests for estimatin alcohol in blood and urine, which were chiefly corrobora tive of common-sense observation If a graph were draw of the percentage of alcohol in the blood of driver charged with being "drunk in charge," the peak of th curve would be at about 0 3%, for at this stage of intoxi cation a driver would draw attention to himself b swerving about the road or hitting something, fo higher concentrations the curve declined, because a this stage the driver would be in the ditch or in coma Mr Frederick Mead, a Metropolitan magistrate, used t say that there was nobody like an experienced police sergeant for judging whether a man was drunk Th doctor had to remember that he contributed only par of the procedure, it was for him to give his medica evidence, but it was the court's responsibility to decide whether the accused was under the influence of drink

Mr Nickolls agreed with Dr Camps that the occasiona drinker who had a few too many was a much wor menace than the habitual toper He had known driver who were drunk when they learnt to drive and would probably have been completely unable to drive if the had ever been sober

If blood or urine was collected for an alcohol estima tion, it was essential to make sure that the receptacle had not been cleansed with spirit or 'Dettol', the same applied to hypodermic syringes and needles

There was great difficulty in obtaining convictions unless one had a cast iron case Magistrate, judge, and juryman were all reluctant to convict, for each one felt "There but for the grace of God " One had literally to shame them into giving a conviction, and the doctor should remember that he had a duty to the public

Dr R D LAWRENCE spoke of the diabetic driver In 1927 he and Dr Otto Leyton had discussed with high police officials the question of the diabetic's fitness to drive, and it had been decided that patients taking insulin were safe as drivers From time to time hypo glycæmia gave rise to a road accident, but such cases were relatively infrequent Any diabetic on insulin especially if he was taking the long acting zinc protamine

Letters to the Editor

PRESCRIBING OF SOPORIFICS

SIR,—A recent account in the daily press must have caused dismay to medical readers. If correctly reported, it appears that a coroner has commented on, and by implication censured, a medical practitioner for allowing the issue of 40 'Seconal' capsules to a patient, thus giving four times the lethal dose into her possession.

Now this is a normal practice. and the only one which is possible for general practitioners or consultants in hospital or private practice. To issue a few sleeping-tablets each week would not deter a determined would-be suicide from carrying out his intent. It is a simple matter to save up the requisite quantity of capsules to procure a fatal dose. Even if all drugs were refused, is it seriously contended that a patient in despair could not take his life? Are we to expect legal strictures on the Gas Board for issuing in unlimited quantities a deadly and insidious poison to the populace?

Note that in the case reported the woman was in hospital because she had taken an overdose of drugs; yet she killed herself by jumping from a third-floor window.

London, W.1. A. H. DOUTHWAITE.

TUBERCULOSIS IN GLASGOW

SIR,—Dr. Brailsford's letter (May 9) shows that even a leader of our profession need not be immune from a common confusion of thought about tuberculosis. It is certainly true that overcrowding will assist the dissemination of tuberculous infection, or of any other infection, and that malnutrition will increase the severity of the individual case; but there is no evidence that "good housing and a good standard of living will eradicate the disease." It is here that the confusion arises, and as a result the early eradication of tuberculosis has been confidently predicted by doctors from time to time over the past fifty years. The reason their prediction has not so far been fulfilled is that environmental improvements, while reducing the incidence and mortality of tuberculosis, cannot eradicate it, because the tubercle bacillus is an extremely resilient organism, and it is against the bacillus itself that the final assault must be made.

Dr. Brailsford's "public health" approach to the disease has not, I think, been consciously used by doctors as a means of escape from a difficult situation; but in fact it has served as such, because if tuberculosis is a disease which can be eradicated by an evolutionary process of social improvement, our responsibility as doctors is considerably lightened. We can be grateful that we ourselves have been strong enough to escape a serious tuberculous lesion and pray that succeeding generations will contain higher and higher proportions of well-nourished people living in airy surroundings. It is because of this argument that it has been easy for some of us to push tuberculosis towards the social worker and politician, out of the field of medical science, to object to our "slender resources" being used to treat tuberculosis in "elaborate chest hospitals," and to dissuade our daughters from nursing in them.

Medical science, however, has at last caught up with tuberculosis. The discovery of streptomycin, *p*-amino-salicylic acid, and isoniazid, and the exploitation of these drugs by the thoracic surgeon in evolving almost miraculous therapeutic techniques, have made tuberculosis one of the most curable of all diseases. The use of these drugs and the development of thoracic surgery and mass radiography have resulted, in the United Kingdom during the past five years, in the most rapid and spectacular fall in the death-rate from tuberculosis which has yet been seen in the long history of the disease. In the same period the price of food has steadily increased; and although the standard of living may not have deteriorated greatly, it certainly has not risen. It seems just possible that because of the revolution in treatment the control of tuberculosis is becoming independent of social conditions. If tuberculosis is a serious problem in Glasgow, it follows that there are not enough chest hospitals in Glasgow and not enough consulting chest physicians.

Thousands of tuberculous patients in the United Kingdom will die this year, not because they have been undernourished or lived in slums, but simply because they were unfortunate enough to become infected with tubercle bacilli and could not be admitted soon enough to a chest hospital. If they were suffering from acute appendicitis, hospitals and operating-theatres would be improvised in disused cowsheds, if necessary, to save their lives; but because they have a disease which so many believe can be eradicated by good food and good housing, their deaths will be merely statistics in annual reports.

We must leave the standard of living and the provision of houses to those sincere men and women to whom we give responsibility for these matters, influencing their actions when we feel it necessary to do so as enlightened citizens; and as doctors we must accept tuberculosis as a challenge to medical science, because if we do not, it will always be with us.

Dungannon Chest Hospital,
co. Tyrone, Northern Ireland. E. F. JAMES.

TREATMENT OF TUBERCULOUS MENINGITIS WITH STREPTOMYCIN

SIR,—In April, 1949, an interim report of a sub-committee of the Scientific Advisory Committee[1] was published summarising the results obtained at five Scottish centres which had been set up for the treatment of tuberculous meningitis. That report contained an analysis of the first 81 patients, of whom 52 had been observed for a minimum period of seven months. Among this latter group 61% had died, and of those who survived the majority were progressing favourably.

Although the numbers were too small to allow of accurate statistical analysis, certain tentative deductions were made regarding the main factors which appeared to govern the prognosis. The most important of these were: (1) the most favourable results were obtained in the age-group 4–17 years; (2) patients who were classified as "early" according to a prearranged clinical grouping,* had a better recovery-rate than those classified as "intermediate" or "late"; (3) the observation of the presence of choroidal tubercles was associated with a higher fatality-rate; and (4) in those cases of meningitis where the chest radiograph showed a "snowstorm" appearance, the outlook was also less favourable. Finally, it seemed that the administration of streptomycin by both the intramuscular and the intrathecal route was essential for success, since none of the patients had survived who had received only intramuscular treatment.

When this analysis was made, it was decided to extend the study to include a larger number of patients who would be followed up for a longer period. Accordingly, it was arranged to include in a further analysis all those patients with tuberculous meningitis admitted between September, 1947 (when the units were opened) and September, 1949. During this period a total of 266 patients was dealt with, which, of course, includes the 81 patients who formed the subject of the earlier report. The records of all these patients were reviewed during

* Clinical grouping: *Early*=Minimal physical signs; no neurological signs; not badly confused. *Intermediate*=Definite meningeal and neurological signs present; confused but able to be roused. *Late*=In coma; many neurological signs.

TREATMENT OF WHOOPING-COUGH WITH ANTIBIOTICS

A REPORT BY THE WHOOPING-COUGH SUBCOMMITTEE OF THE ANTIBIOTICS CLINICAL TRIALS (NON-TUBERCULOUS CONDITIONS) COMMITTEE OF THE MEDICAL RESEARCH COUNCIL*

DURING 1950–51 a controlled investigation of the value of chloramphenicol and aureomycin in the treatment of whooping-cough was made in eight infectious-diseases hospitals in England, Scotland, and Northern Ireland.

Plan of the Investigation

Children 0–5 years of age admitted to the eight hospitals with *uncomplicated* clinical pertussis within 21 days after the onset of the earliest symptoms were included in the trials. On admission the patients were divided by sex and placed in one of three age-groups—0–11 months, 12–35 months, and 36–59 months. They were then allocated to one of three treatment groups—the chloramphenicol group, the aureomycin group, or the control group. Children in the control group were given a mixture of lactose and quinine. The drugs were dispensed in cachets, and, as the chloramphenicol was white and the aureomycin yellow, half the control cachets contained white powder and half yellow powder. To make it more difficult for the observer to detect which drug was being given to an individual patient each of the three drugs was made up under three different letters. The order in which patients were allocated to the treatments was determined by placing the nine letters in a randomly determined sequence. A separate sequence was constructed for each series of 9 patients in each age and sex group.

All the cases were given the appropriate treatment for the first 7 days of the observation period, but the amount of the drug differed for each age-group. Children aged 0–11 months were given 1·0 g daily, children aged 12–35 months 1·5 g daily, and children aged 36–59 months 2 g daily. The drugs were administered twice a day in equally divided doses. Administration presented some difficulties because of the bitter taste. Each hospital devised its own methods, and the powder from the cachets was mixed into honey, jam, fruit purée, milk, sweetened condensed milk, or other suitable excipient.

Each child was to be observed for 20 days. Observations were first recorded on the first day of treatment. Each day notes were made of the number of paroxysms observed by the day staff and the night staff, and at the end of each day the sister of the ward was asked to record whether the paroxysms in each case had been on the whole mild, moderate, or severe. Records were made of the frequency of vomiting during or after paroxysms, but the recorded incidence was low, and in the analysis no useful information was obtained. The occurrence of toxic effects of the drugs was also noted, including vomiting immediately after administration.

It was expected that, though only uncomplicated cases were to be taken into the investigation, some children might develop complications during the period of treatment and observation. For the purpose of the inquiry, a complication was defined as any infective condition associated with whooping cough which the physician in charge considered to be severe enough to require immediate treatment with sulphonamides or antibiotics. In such cases when they occurred during the 7 day treatment period the administration of the trial drugs was stopped. The physicians treated the cases as they thought best. Observations on the number and severity of the paroxysms were continued and all the complicated cases were included in the analysis.

Description of Treatment Groups

Numbers of Cases.—Altogether records were completed for 317 patients, but the records for 23 cases were excluded.

In 7 the appropriate drug was not available at the time of admission or the wrong dosage scale was used, in 3 the diagnosis was doubtful, 1 child had been treated with chloramphenicol and 1 with aureomycin before admission, 2 children developed salmonella infections and 1 developed Sonne dysentery within 4 days of the start of treatment; these patients were removed to other wards. 1 child was found to be infected with *Hæmophilus parapertussis*. 3 children were removed from hospital by their parents early in the observation period. 4 children (3 on aureomycin and 1 on chloramphenicol) vomited the drug repeatedly and attempts to continue administration had to be abandoned.

The analysis was therefore made on the records for 294 cases. The distribution of cases by age and by treatment group is given by hospitals in table I. 98 patients were in the chloramphenicol group, 96 in the aureomycin group, and 100 in the control group. The number in each treatment group was similar for all hospitals together and for each hospital separately. The number of children treated in Neasden, St Ann's General, and Northern Ireland Fever Hospitals was small and these hospitals were grouped together.

TABLE I—RESULTS AFTER OBSERVATION OF AT LEAST 2 YEARS AND 3 MONTHS IN CASES OF TUBERCULOUS MENINGITIS WITHOUT AND WITH "SNOWSTORM" APPEARANCE OF CHEST RADIOGRAPH

—	No. of patients treated	Results		
		Died	Unsatisfactory	Good
Without "snowstorm" lung	181 *(100%)*	94 *(52%)*	16 *(9%)*	71 *(39%)*
With "snowstorm" lung	85 *(100%)*	47 *(55%)*	4 *(5%)*	34 *(40%)*
Total	266 *(100%)*	141 *(53%)*	20 *(8%)*	105 *(39%)*

December, 1952—i.e., after a minimum follow-up period of 2 years and 3 months.

Table I gives the results of treatment for the two main groups of cases—namely, patients with tuberculous meningitis without an accompanying "snowstorm" radiograph of the chest, and patients who, at any time during their treatment, presented evidence of both manifestations of the disease. It will be observed that for the series as a whole and for each of the two groups the proportion of results classified as "good" is the same—namely, approximately 40%.

Subdivision of the cases into the three grades—early, intermediate, and late—has confirmed the original impression that the best results have been obtained in those patients who were regarded as "early" on admission, for in this group the proportion of satisfactory recoveries approaches 60%. The general validity of this clinical assessment as a prognostic guide is supported by the fact that, in those assessed as "early" on admission, death was unusual during the initial period of treatment, whereas in those assessed as "late" a high proportion of the deaths occurred during the first 4 weeks in hospital (table II).

Table II shows the number of deaths, the weekly fatality-rate, and the number of survivors at intervals following admission to hospital. As would be expected, the mortality among survivors in each period progressively diminishes with the passage of time.

This analysis may be briefly summarised. During a period of 2 years, 266 patients with tuberculous meningitis were treated with streptomycin at five Scottish centres. A follow-up of these patients 2 years and 3 months after the admission of the last case shows that 105 (39%) were alive and regarded as excellent recoveries; a further 20 patients were alive although their condition was regarded as unsatisfactory; and the remainder—141—have died.

It seems desirable to correct an earlier impression regarding the importance of the demonstration of a "snowstorm" radiograph in patients with meningitis. In this larger series, such a finding seems of little prognostic value. On the other hand, the assessment of the patient when treatment is begun, despite the fact that it is based on somewhat imperfect clinical data, does constitute a useful prognostic guide. It is apparent that the clinical findings used in making this assessment reflect a gradation of "severity," and that in a proportion of the "late" cases the administration of streptomycin produces little alteration in the steady deterioration of the patient.

TABLE II—DEATHS, FATALITY-RATES, AND SURVIVORSHIP

Weeks after admission	—1	—2	—4	—8	—16	—52	—116
No. of patients alive at beginning of period	266*	247	232	217	205	175	129
Deaths during the period E	0	0	1	2	6	17	2
I	6	5	4	7	16	24	2
L	13	10	10	3	8	5	0
	19	15	15	12	30	46	4
Average weekly fatality-rate (%) among survivors	7	6	3	1·4	1·8	0·7	0·05

*In the series 28% were classified as "early," 49% as "intermediate," and 23% as "late."

CIRRHOSIS: LIGATION OR ANASTOMOSIS?

SIR,—Professor McFadzean and Mr. Cook (March 28) plead that hepatic-artery ligation has been developed in an attempt to find a safe and effective substitute for portacaval anastomosis. They admit that portacaval shunts prevent the recurrence of hæmatemesis and have a favourable effect on the ascites in the majority of these cases. Similar remarks were made in your editorial last year.[1]

I do not believe that any operation should be advocated simply because it is technically difficult, but neither should an effective operation be abandoned because of its difficulty. If this view were adopted we would all still be doing gastrojejunostomy instead of gastrectomy for chronic duodenal ulcer! Furthermore, I believe that the difficulties and dangers of portacaval anastomosis have been grossly overestimated. The early results in this unit have been reported elsewhere[2] and it was then noted that the operation carried a high mortality-rate in patients in whom splenectomy had not been performed, but that in the first 9 patients in whom splenectomy had been performed as a preliminary measure there had been only 1 operative death. Since these cases were reported 6 further direct portacaval shunts have been done without operative death. The operation can be completed within two and a half hours. Only 1 patient, operated on four years ago, has had hæmatemesis, and the results of treatment on the whole have been very satisfactory.

Against this background must be considered the results of hepatic-artery ligation as reported, and also as carried out in this unit. The clinical material in McFadzean and Cook's series is presumably similar, for in Hong-Kong it is largely chance which determines whether the patient finds his way into the medical unit and has his hepatic artery tied, or into the surgical unit to get an Eck fistula.

In this unit 4 patients have been subjected by way of a trial to hepatic-artery ligation. The first died with portal vein thrombosis, and the remaining 3 went steadily downhill. It was noted at operation that the fall in portal pressure, measured directly with a manometer, was quite inconstant after ligation of either splenic or hepatic arteries. Furthermore, it must be remembered that the peripheral resistance within the liver is increased in cirrhosis and flow is therefore dependent on maintenance of an adequate pressure. If the pressure in the portal vein falls and the hepatic arterial supply is removed, the total flow through the liver must fall. If the portal vein only is interrupted, blood continues to reach the liver at a high pressure through the hepatic artery and in these circumstances maintenance of adequate liver function in man is possible.

It is well known that in a certain number of patients with cirrhosis splenectomy alone improves the clinical condition, and I am not yet convinced that the improvement which follows ligation of the hepatic artery, combined

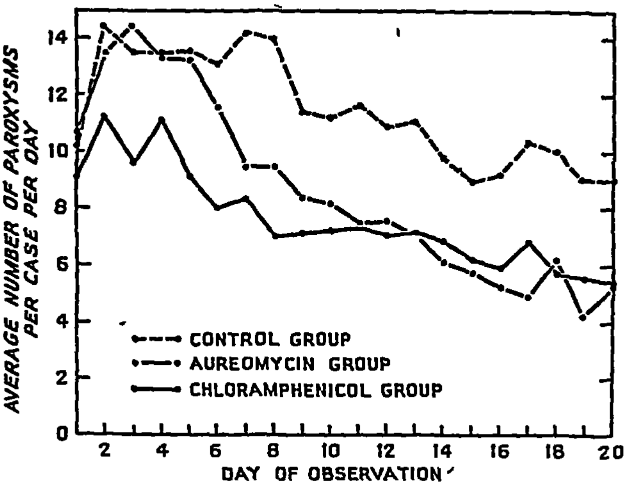

Fig 1—Early cases

Sex distribution—More females than males were treated in the investigation In the chloramphenicol group 53 1% were females, in the aureomycin group 56 3%, in the control group 55 0%, and in all groups together 54 8% As the proportion of females in each group was similar, no separate analysis by sex was made From inspection it did not appear that females fared better or worse than males

Confirmation of Diagnosis—All suitable cases which on clinical grounds were considered to be suffering from whooping cough were taken into the investigation In order to confirm the clinical diagnosis swabs were taken on admission and an attempt was made to get a history of other cases in the family or neighbourhood *H pertussis* was isolated from 47% of the cases—44% in the chloramphenicol group, 49% in the aureomycin group, and 47% in the control group A history of associated cases was obtained from 60—59% in the chloramphenicol group, 65% in the aureomycin group, and 56% in the control group

Duration of Observations—The intention was to observe each case for 20 days from the beginning of treatment, but some patients were discharged before the full period of observation was completed The numbers lost at various stages in each group were similar (see table III) The records of these cases were included up to the time the patients left hospital

Results

The results in the three groups were assessed by analysing (*a*) the number of paroxysms per case per day, (*b*) the severity of the paroxysms, (*c*) the number of complicated cases, (*d*) the number of deaths, and (*e*) the bacteriological findings at intervals during the period of observation The cases were divided into three types depending on the duration of symptoms before treatment was begun

Early cases were defined as those with symptoms for 1-8 days before treatment began There were 85 early cases—28 on chloramphenicol, 29 on aureomycin, and 28 controls

Intermediate cases were defined as those with symptoms for 9-15 days before treatment began In this category there were 147 cases—50 on chloramphenicol, 49 on aureomycin, and 48 controls

Late cases were defined as those with symptoms for 16-21 days before treatment began 62 were placed in this category —20 on chloramphenicol, 18 on aureomycin, and 24 controls

The date of the beginning of the illness was taken as the day on which the earliest symptoms—cough or coryza —began, and *not* as the day when the cough became paroxysmal Complete accuracy in ascertaining the day of the onset of the first signs of illness was not always possible, but cases on all three treatments were subject to the same degree of error

A separate analysis of the records of children on chloramphenicol and aureomycin was made No clear difference between the effects of the two antibiotics was observed, this is illustrated in the graphs Except for consideration of complications and deaths, the two groups were combined and are referred to as the "treated group"

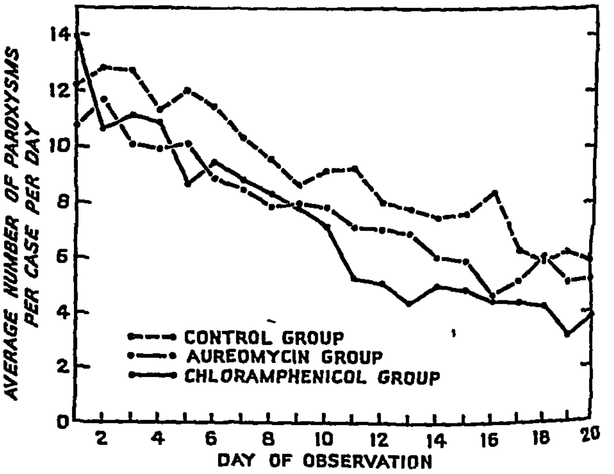

Fig 3—Late cases

NUMBERS OF PAROXYSMS

The average number of paroxysms per case was calculated separately for each of the 20 days of observation The results for each day are shown in the graphs and by 4 day periods in table II The average number of paroxysms per case in the treated group was less than in the control group for the early, intermediate, and late cases, and the differences were consistent throughout the period of observation In the day-by day analysis, the differences in the average number of paroxysms per case on days 6, 7, 8, and 9 (i e, around the end of the treatment period on day 7) were for early cases 3 2, 5 2, 5 7, and 3 7, for intermediate cases 1 0, 1 9, 1 4, and 1 6, and for late cases 2 3, 1 8, 1 5, and 0 8 The only large differences were those observed in the early cases where for example on day 8 the [illegible] 5 7 paroxysms This finding was [illegible] (difference/standard error = 3 2) In the intermediate and late cases the treated children had on the average about 2 paroxysms per day less than the control children

The information on paroxysms was then analysed by calculating for the 2nd, 8th, 14th, and 20th days of observation the percentages of cases with 0-9, 10-19 and 20 or more paroxysms (table III) By this method

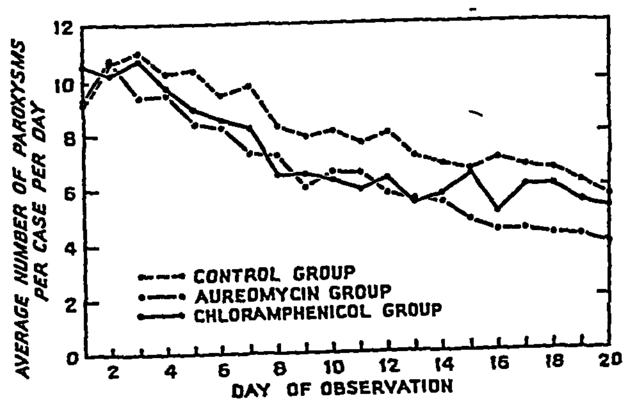

Fig 2—Intermediate cases

with splenectomy is due to the ligation rather than to the splenectomy.

These considerations have led me to discard the operation of ligation of the hepatic artery and I continue to advocate splenectomy followed by portacaval anastomosis for any patient with cirrhosis, splenomegaly, and œsophageal varices.

CONTRACEPTIVE TECHNIQUE

SIR,—The letter from the managing director of Ortho Pharmaceutical Ltd. should not satisfy anyone in charge of a birth-control clinic, and does not satisfy me, though it advertises further the contraceptives I am warning people about. The "diaphragm and jelly" Mr. George praises I have long shown to be a not entirely satisfactory technique.[1] Though theoretically it would be very nice to have a suppository or substance that would do away with the necessity for any diaphragm cap or barrier, there are reasons which make this unlikely of achievement. Mr. George claims that their advertised product —'Preceptin Vaginal Gel'—is safe without any barrier.

First let me say it has to be placed with an applicator, and for general contraceptive use I condemn all methods involving the use of an applicator, which has many bad features. Further, a method involving the use only of a jelly-like substance ignores the fact that in coitus the sperm may be ejaculated directly into the uterus, when none of the substance's alleged unique capacity to destroy sperms would be able to take effect.[2]

The Ortho Research Foundation speaks of "thousands of patients." What degree of safety after at least one year's, and preferably two years', consistent use of this as the only contraceptive do they claim? We should be given also one or two addresses of recommended clinics in this country where this contraceptive has been consistently used, and the degree of success they record.

THE BRACHIAL-PALSY HAZARD

SIR,—Though the Law may have to concern itself with a particular injury or an isolated event, doctors must try to regard the whole patient and his whole welfare. Recent interest in brachial-plexus injury subsequent to certain operating-table positions seems to illustrate this matter.

Let us, for argument's sake, admit that there is a risk of brachial-plexus injury following maintained abduction of the arm under anæsthesia. I believe that there are instances when the risk should forthrightly be accepted in the patient's interest.

Sometimes the continuance of an intravenous infusion is of critical importance to the patient because of collapse. Sometimes sudden and unpredicted interruption of the flow of the infusion might disrupt the smooth course of anæsthesia given by the method judged best for the patient's survival, and such sudden disruption at a critical point in the operation could have grave consequences. In patients in a shocked state veins in the leg are often unsatisfactory, and an infusion into a forearm vein can easily fail unless the arm is accessible so that attention can be given immediately when needed. Unless the arm is abducted such attention is either impossible or imperfect. If the arm be only a little abducted the surgeon may be hampered by it and the patient's interests thereby damaged.

Even though it may expose me to the risk of being deemed negligent, I shall continue as occasion requires to place an infusion in a forearm vein, and abduct the arm onto an arm-board so that I can be as sure as humanly possible that the flow continues. I shall do this because I believe that the conscientious application of knowledge and judgment to the patient's whole welfare will not infrequently demand it; though I shall be fully aware of the small risk to his brachial plexus.

Department of Anæsthesia,
Royal Victoria Infirmary,
Newcastle upon Tyne.

E. A. PASK.

⁂ Dr. Pask can, we believe, pursue his course safely for the patient if he makes one small concession to the brachial plexus: by using the Jackman arm-rest[1] he can prevent the abducted arm from falling below the coronal plane of the body. At the same time, we should point out that many other devices for protecting the brachial plexus are already in successful use.[2]—ED. L.

INTESTINAL OBSTRUCTION IN INFANTS

SIR,—It was never the intention in my letter of April 4 to decry in any way the invaluable part played by special centres in the advancement of neonatal surgery, and I question whether such an interpretation is justified. Pædiatric surgical centres in Boston, Liverpool, and Stockholm, among others, have in a few years turned a mortality-rate of 75% in intestinal obstruction of the newborn (excluding meconium ileus) into a survival-rate of 75% or better—truly a remarkable achievement.

Progress in medicine and surgery characteristically follows a pattern by which one or more main centres develop new methods of treatment or new surgical techniques, which are later successfully adopted by others. Surely this process can be profitably applied to abdominal surgery in the newborn, where early diagnosis and treatment are essential.

Halifax General Hospital. **W. P. SWEETNAM.**

PEPTIC ULCERATION

SIR,—I was interested in Dr. Csato's account (May 16) of treatment of peptic ulceration with injections of chorionic gonadotropin.

Some time ago I was struck by a statement by a patient with duodenal ulcer that her symptoms always remitted when she was pregnant. As she had failed to respond to the usual medical remedies, I gave her a course of ethinylœstradiol sublingually (to avoid the irritant effect of the drug on the gastric mucosa). There was an immediate resolution of symptoms in 2–3 days; but when she suffered a further exacerbation some 6 months later, there was complete failure to reproduce the same effect. Neither did she respond to ethisterone given in like manner. Since then I have tried both hormones in 5 other cases, and methyltestosterone in 3 male patients. Symptoms have been completely relieved by ethisterone in 1 case, and by ethinylœstradiol in another; but in the remaining 6 cases there was no effect. In 1 case methyltestosterone greatly aggravated the pain. In view of Dr. Csato's observations, I intend to treat some further cases with injections of progesterone, as opposed to the less reliable oral preparation.

There is, perhaps, a slight tendency to take for granted the natural history of diseases, without inquiring more deeply into possible causes for spontaneous remissions and variations. Thus pregnancy has often been classed as one of many intercurrent conditions which may cause remission in such diverse diseases as peptic ulceration, disseminated sclerosis, and rheumatoid arthritis. Yet this observation on rheumatoid arthritis was one of the factors leading directly to the discovery of cortisone.

TABLE II—AVERAGE NUMBERS OF PAROXYSMS PER CASE PER DAY IN 4-DAY PERIODS

—		Days 1–4 C*	Days 1–4 T†	Days 5–8 C	Days 5–8 T	Days 9–12 C	Days 9–12 T	Days 13–16 C	Days 13–16 T	Days 17–20 C	Days 17–20 T
ALL CASES	Average number of paroxysms per case per day	11 5	10 7	10 9	8 6	9 0	6 7	7 9	5 5	7 1	5 0
	Difference	*0 8*		*2 3*		*2 3*		*2 4*		*2 1*	
EARLY CASES	Average number of paroxysms per case per day	14 9	11 6	13 6	9 6	11 2	7 5	9 7	6 2	9 5	5 4
	Difference	*3 3*		*4 0*		*3 7*		*3 5*		*4 1*	
INTERMEDIATE CASES	Average number of paroxysms per case per day	10 3	10 0	9 4	7 9	7 9	6 2	6 9	5 3	6 3	5 0
	Difference	*0 3*		*1 5*		*1 7*		*1 6*		*1 3*	
LATE CASES	Average number of paroxysms per case per day	12 3	10 8	10 9	8 8	8 7	6 8	7 8	5 2	6 0	4 7
	Difference	*1 5*		*2 1*		*1 9*		*2 6*		*1 3*	

* C = control group † T = treated group

also the differences between the control and treated groups were greatest in the early cases For instance on day 2 the percentages of early cases with 0–9, 10–19, and 20 or more paroxysms were similar in the two groups, but on days 8, 14, and 20 respectively 72%, 80%, and 90% of the treated children had fewer than 10 paroxysms per day compared with 40%, 58%, and 64% of the control children These differences were statistically significant (differences/standard errors = 2 6, 2 2, and 2 7)

SEVERITY OF PAROXYSMS

As mentioned earlier, the sister of the ward, who did not know which drug was given to individual patients, was asked to record each day during the observation period whether she considered the paroxysms in each case had been on the whole mild, moderate, or severe For the analysis of this information the 20 day observation period was divided into the five 4-day periods The results for the early, intermediate, and late cases are given in table IV The greatest differences between the treated and control groups were in the early cases For example the proportion of early control cases in which the paroxysms were described as absent or mild increased from 22% in the first 4 day period to 29% in the fifth 4 day period, but in the treated cases the percentages increased from 17 to 66 Between the first and fifth 4 day periods the proportion of control cases with severe paroxysms fell from 41 to 23% while the proportion of treated cases fell from 27 to 4%

In the early cases the differences between treated and control groups in the percentages of cases where the paroxysms were absent or mild were statistically significant for the third, fourth, and fifth 4 day periods (differences/standard errors = 4 4, 5 8, and 6 2) In the intermediate cases the differences in the percentages of cases where the paroxysms were absent or mild were statistically significant for the same three periods (differences/standard errors = 2 7, 3 1, and 3 9) It appeared that the drugs influenced the severity of the paroxysms to a greater degree than they affected the numbers of paroxysms in the intermediate cases*

TABLE III—PERCENTAGES OF CASES WITH 0–9, 10–19, AND 20 OR MORE PAROXYSMS ON THE 2ND, 8TH, 14TH, AND 20TH DAYS OF OBSERVATION

COMPLICATED CASES AND DEATHS

19 patients developed respiratory complications during the observation period—7 in the control group (3 bronchopneumonia, 2 bronchitis, 1 lobar pneumonia, and 1 pleural effusion with atelectasis), 7 in the aureomycin group (2 bronchopneumonia, 2 bronchitis, 2 lobar pneumonia, and 1 pleural effusion with atelectasis), and 5 in the chloramphenicol group (3 bronchopneumonia and 2 bronchitis) 3 cases in the control group and 2 cases in the chloramphenicol group occurred during the period the drug was being administered All cases in the aureomycin group and the remaining cases in the other groups occurred after the end of the treatment period In addition 3 cases, 1 in each treatment group, were fatal, in the control group a male aged 6 weeks developed bronchopneumonia on the 5th day of observation and in spite of treatment with sulphonamides and penicillin died on the 10th day of observation, in the aureomycin group a male aged 7 months developed convulsions on the 14th day of observation and died the following day, in the chloramphenicol group a female aged 1 year developed widespread collapse of the lungs about the 7th day of observation and died on the 11th day of observation None of the complicated or fatal cases occurred in patients treated within 8 days of the onset of symptoms

BACTERIOLOGICAL RESULTS

Most cases were swabbed on or about the 1st, 2nd, 3rd, 8th, and 11th days of observation In the third

COMPRESSION OF CERVICAL CORD AND CERVICAL SPONDYLOSIS

SIR,—In connection with the article by Sir Charles Symonds (March 7) on the interrelation of trauma and cervical spondylosis in cervical-cord compression, I should like to record the following case.

The patient, aged 71, was admitted to Addenbrooke's Hospital on March 21, 1952. That afternoon he had been for a walk, but felt dizzy and came home by bus. On alighting he fell, but he was unable to give an account of the exact circumstances. Eye-witnesses said that it looked as if he had fainted and had fallen on to his head; it was thought that he had temporarily completely lost the use of his legs and arms. When admitted to the casualty department he could talk and was rational; he said he had lost the use of his arms and legs, and he complained of severe pain in his fingers and hands.

There was a small abrasion over the vertex. Pulse-rate 36 per min.; blood-pressure 160/90 mm. Hg. The patient's arms were held abducted at the shoulders, and the elbows were flexed. There was little voluntary movement of the upper arms apart from weak flexion of the elbows and abduction of the shoulders. Complete paralysis of the lower limbs had been reported, but during this examination he regained some weak power of flexion of the hips and knees. Reflexes were as follows: biceps, triceps, and supinator jerks absent on the right side, just elicited on the left side; abdominal reflexes absent; knee-jerks and ankle-jerks present; plantar reflex equivocal on the right side, extensor on the left side. Neck movements, particularly extension, produced pain in the arms and hands. There was some tenderness over the spinous processes of C3 and C4.

Radiographic examination showed no evidence of dislocation or fracture of the cervical spine. Some diminution of the disc spaces C4–5 and C5–6 was noted; but there was only slight lipping of these vertebral bodies, and there were only slight osteo-arthritic changes.

Lumbar puncture yielded cerebrospinal fluid under pressure of 150 mm. water; protein 55 mg. per 100 ml.; Queckenstedt test indicated partial block on extension, slight relief on flexion.

Electrocardiography showed 2 : 1 heart-block.

Course.—The patient was admitted and rested flat in bed. Power was gradually regained in the lower limbs, but severe paræsthesia in the hands and forearms persisted. Next day there was still little power in the hands or forearms, though the biceps showed some improvement and there was full active movement of the lower limbs. On March 23 pain and temperature sensation were noted absent in his legs, but position sense was unimpaired. Attempts to relieve the pain in the arms by traction on the head only exacerbated it, and retention of urine added to the patient's distress. Despite antibiotics and parental therapy, his general condition gradually deteriorated, and on March 29 he died of uræmia and bronchopneumonia.

Necropsy.—There was almost complete prolapse backwards into the spinal canal of the intervertebral disc between the 4th and 5th cervical vertebræ, narrowing the spinal canal at this point: the narrowing was greater to the left of the midline. There was also incomplete prolapse of the intervertebral disc between the 5th and 6th cervical vertebræ, causing a slighter narrowing of the spinal canal. Some portions of protruded material lay beneath the posterior longitudinal ligament, thus connecting these two prolapsed intervertebral discs. Recent hæmorrhage into the remains of the affected discs suggested that these changes were recent and traumatic. The spinal cord had evidently suffered some compression at the site of the maximum narrowing of the spinal canal, but it showed no gross abnormality to the naked eye. Section of the cord at the level of the disc prolapse showed definite acute degenerative changes consistent with recent trauma; the changes were mainly in the lateral columns.

The lungs showed bilateral severe bronchopneumonia affecting the lower lobes. An infarct was present in the right upper lobe. In the heart there was no gross change apart from some atheroma of the coronary arteries with slight narrowing of the right coronary artery.

In this case there was sudden spinal-cord compression, probably due to an acute injury, associated with prolapse of two intervertebral discs. There is no clear evidence as to whether it was a flexion or extension injury. The cause of the fall may have been heart-block. Apart from narrowing of the intervertebral discs C4–5 and C5–6 there was little radiographic evidence of cervical spondylosis. This discrepancy between the relatively normal radiographic findings on the one hand and the pathological findings on the other corresponds with that found by Brain et al.,[1] who correlated the radiographic and myelographic findings in a number of similar cases. The simultaneous prolapse of two intervertebral discs corresponds with multiple lesions described by Brain et al., but the protrusion of disc material beneath the posterior longitudinal ligaments is unusual. The changes in the lateral portions of the cord may account for the dissociated sensory loss in the legs and the paræsthesia in the arms. This distribution of microscopic changes in the cord is in contrast to those described by Sir Charles Symonds in case 4 of his article, but corresponds quite remarkably with the findings of Bedford et al.[2]; it suggests that they may be related to the attachment of the denticulate ligaments to the lateral margin of the spinal cord.

I would like to thank Mr. T. J. Fairbank, consultant orthopædic surgeon, for permission to publish this case, and Dr. A. M. Barrett, university pathologist, for the description of pathological findings in this case, which he discussed at a clinico-pathological conference of Cambridge University Medical School.

Addenbrooke's Hospital,

THE ILLEGIBLE CANDIDATE

SIR,—I greatly appreciate the timely and humane letter from Sir John Conybeare (May 16).

I should not dream of penalising an examination candidate for bad writing. Indeed, I regard any extra labour involved in reading an illegible script as an opportunity of repaying the debt I owe to my own examiners.

Department of Medicine,
University of Birmingham.

W. MELVILLE ARNOTT.

DIAGNOSIS OF ACUTE MENINGITIS IN INFANCY

SIR,—Dr. Haworth's article is most timely, in view of your recent leading article, Hazards of Lumbar Puncture, and the correspondence it has provoked. However, I do not think pædiatricians are likely to be deterred from resorting to lumbar puncture on the slightest suspicion of meningitis, where the hazards of tardy diagnosis far outweigh any other consideration.

It is good that Dr. Haworth stresses once again the difficulty in diagnosis of acute meningitis in infants, but in giving indications for lumbar puncture he made no mention of convulsions. Ounsted[3] said: "It follows that any small child who has had an *unexplained* febrile seizure should be admitted to hospital, and that, unless some definite contra-indication exists, a lumbar puncture should be done without delay." Profiting by past mistakes, I now make it a rule to perform a lumbar puncture on any infant under twelve months of age who has just had a convulsion for the *first time*. Indeed, I am not deterred by the presence of an obvious focus of infection such as an acute otitis media or pneumonia, for meningitis may well co-exist.

It is noteworthy that, in the series analysed by Dr. Haworth, cases 4, 8, and 11 would have been diagnosed ante mortem if this rule had been applied.

The newborn period is a time of especial diagnostic difficulties, and lumbar puncture must then be considered as part of a routine investigation in an "ill baby." The day seems not far distant when there will be

V = 11th day of observation (day 11) *or* day 10 *or* day 12 *or* day 13

and fourth intervals (see footnote to table v) the percentage of positive cases was less in the treated than in the control groups for early, intermediate, and late cases. The differences for cases of all types at these intervals were statistically significant (differences/standard errors = 2·3 and 3·4). In the treated group of early cases the percentage of cases from which *H. pertussis* was isolated increased from 4·4 in interval IV to 10·4 in interval V. As the same children were not swabbed in the two intervals this did not mean that some cases became swab-positive after treatment had been completed. When the cards were scrutinised it was found that none of the children who became swab-negative were positive when swabbed later.

TOXIC EFFECTS

Presumed toxic effects were noted in 28 cases—12 in the chloramphenicol group, 15 in the aureomycin group, and 1 in the control group. The effects noted were:

Vomiting.—7 on chloramphenicol, 11 on aureomycin, and 1 control.

Anorexia.—3 on chloramphenicol and 2 on aureomycin.

Diarrhœa.—2 on choramphenicol.

Redness of Buttocks.—1 on aureomycin.

Urticarial Rash.—1 on aureomycin.

Summary and Conclusions

In a strictly controlled investigation 98 children 0–5 years of age were treated with chloramphenicol, 96 with aureomycin, and 100 with an inert powder (lactose and quinine). The patients were given the drugs twice daily for 7 days. For 20 days from the 1st day of treatment the number and severity of paroxysms and the occurrence of toxic effects and complications were noted. In addition, swabs for isolation of *H. pertussis* were taken on admission and at intervals afterwards.

When cases which had symptoms for 1–21 days before the beginning of treatment were considered together, the benefit to the treated cases, though consistent during the period of observation, was small. If attention had been directed solely to the straightforward comparison of the whole of the treated and control groups it would have been concluded that the results were disappointing and that chemotherapy failed to produce a clear-cut clinical cure. In cases which were treated within 8 days from the onset of the earliest symptoms the differences between the groups were greater, and some of the differences were statistically significant. Even with early cases, however, the effect of the drugs was not dramatic. No difference was detected between the effect of aureomycin and chloramphenicol.

On the 3rd and 8th days of observation but not on the 1st, 2nd, and 11th days of observation the proportion of patients from whom *H. pertussis* was isolated was greater in the control group than in the treated group.

These findings are in general agreement with those of Wehrle et al. (1951) and LaBoccetta and Dawson (1952), and it may be reasonable to speculate on the significance of the results in relation to our scanty knowledge of the pathogenesis of the disease. In an acute infectious disease it might be expected that elimination of the infecting agent would be followed by rapid disappearance of the signs which that agent initiated. The failure to observe such an immediate amelioration in whooping-cough might support a view that infection with *H. pertussis* sets in train a sequence of events which, once it has started, is not greatly affected by elimination of the pathogen. The present study suggests that early recognition and early antibiotic therapy of whooping-cough may help to reduce the severity of the infection, but that little is to be gained from antibiotic treatment of cases in which even slight symptoms have been present for more than a week.

FAMILIAL CRETINISM

DOUGLAS HUBBLE
M.D. Lond., M.R.C.P.
PHYSICIAN, DERBYSHIRE ROYAL INFIRMARY AND
DERBYSHIRE HOSPITAL FOR SICK CHILDREN

WHEN cretinism occurs in regions where goitre is not endemic it is known as *sporadic* cretinism. This is the common type of cretinism seen in this country, and it is usually accompanied by no evidence of a goitre. Hilton Fagge, of Guy's Hospital, observed in 1871 that no vestige of a thyroid gland could be found in sporadic cretins, and he contrasted this with the "bronchocele" seen in endemic cretinism. The published reports of the histology of the thyroid gland confirm that there is an atrophy of this gland without any evidence of colloid formation or other active gland structure. It may be assumed, as a working hypothesis, that such atrophy of the thyroid gland could either be due to a primary failure of the thyrotropic hormone or else to some failure in the gland, either developmental or destructive. A primary failure of the thyrotropic hormone has not yet been established as a cause of cretinism. Where there is a primary failure of the gland, it may be assumed that there is an excess of thyrotropic hormone circulating, because the secretion of this anterior pituitary hormone is inversely regulated by the amount of circulating thyroxine. The gland, however, is incapable of response to this stimulus.

Endemic cretinism occurs in regions where goitre is endemic because of a deficiency of naturally occurring iodine. The goitrous thyroid resulting from severe iodine as many quips in pædiatric circles about the neglected lumbar puncture as there are about that old favourite, the rectal examination.
